Agent, Environment, Perceptions, and Actions

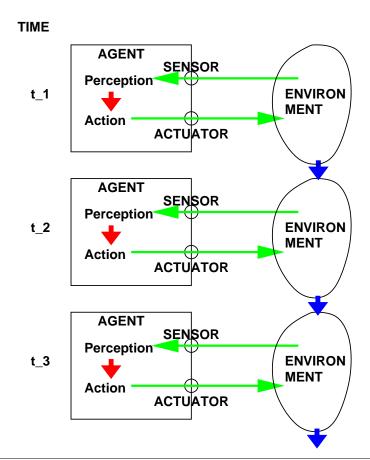

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

Artificial Intelligence / 1. The Agent Metaphor

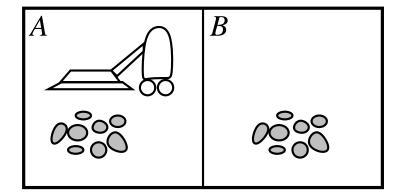

Perception Sequence and Action Sequence

Silly Example: The vacuum-cleaner world

Perceptions: pairs of

• location of the vacuum-cleaner: square A or square B

• content at that location: clean or dirty

Actions: move left, move right, suck dirt, do nothing.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

Artificial Intelligence / 1. The Agent Metaphor

Silly Example: The vacuum-cleaner world

Perception sequence	action sequence
(A, clean)	right
(A, dirty)	suck
(B, clean)	left
(B, dirty)	suck
(A, clean), (A, clean)	?

Silly Example: The vacuum-cleaner world

Perception sequence	action sequence
(A, dirty)	suck
(A, clean)	right
(B, dirty)	suck
(B, clean)	left
(A, clean), (B, clean)	noop
(B, clean), (A, clean)	noop

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

5/44

Artificial Intelligence / 1. The Agent Metaphor

Components of Environments

Environements consist of four components (so-called "PEAS" model):

Performance measure:

describes successful behavior of an agent; the goal.

Environment:

describes what other entities there are to interact with.

Actuators:

describes the actions an agent can take and how they influence the environment.

Sensors:

describes the perceptions available to an agent.

Properties of Environments (1/2)

deterministic - stochastic:

deterministic: the next state is completely determined by the previous state and the action.

static - dynamic:

static: the state of the environment does not change while the agent deliberates,

e.g., a turn-based game.

fully observable - partially observable:

fully observable: all properties of the true state that are relevant to take the optimal action are perceived, e.g., in chess.

partially observable: e.g., the vacuum world with information just about the actual location.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

7/44

Artificial Intelligence / 1. The Agent Metaphor

Properties of Environments (2/2)

discrete - continuous:

discrete time: e.g., measured in steps.

discrete states: e.g., counts; locations on a grid; etc.

discrete perceptions: e.g., counts; locations on a grid; etc.

(same as for states).

discrete actions: e.g., just steering left/right (but not by a continuous angle).

Episodic - sequential:

episodic: actions do only influence the next state, but not any later states.

Single agent – multiagent:

multiagent: several agents act in the environment. (cooperative vs. competitive scenarios)

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

Artificial Intelligence / 2. Problem Descriptions

Problems

A **problem** consists of six components (here 1–4):

super state space: set $X^{\#}$

a set of entities that describe the state of the environment, i.e., the actual configuration at a given point in time.

action space: set A

a set of entities that describe the actions that an agent may perform.

initial state: element $x_0 \in X^{\#}$ the state the agent starts in.

successor function: partial function succ : $X^{\#} \times A \rightarrow X^{\#}$

triples x, a, x' consisting of

- previous state x,
- possible action a in that state and
- follow up state x'

(for deterministic environments)

Problems / State space

Initial states and successor function implicitly define the **state** $\mathbf{space}\ X$ by enumeration:

$$X:=\bigcup_{n\in\mathbb{N}}\operatorname{succ}^n(x_0)\subseteq X^\#$$

where succⁿ denotes the n-th power of succ(\cdot , A), i.e.,

$$\begin{aligned} &\operatorname{succ}^0(x) = x, \\ &\operatorname{succ}^1(x) = \operatorname{succ}(x,A) = \bigcup_{a \in A} \operatorname{succ}(x,a), \\ &\operatorname{succ}^2(x) = \operatorname{succ}(\operatorname{succ}(x,A),A) = \bigcup_{a \in A} \bigcup_{a' \in A} \operatorname{succ}(\operatorname{succ}(x,a'),a) \text{etc.} \end{aligned}$$

Obviously,

$$x_0 \in X$$

and succ can be restricted to

$$\operatorname{succ} \subseteq X \times A \times X$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

10/44

Artificial Intelligence / 2. Problem Descriptions

Problems

A **problem** consists of six components (here 5–6):

goal test:
$$g: X \rightarrow \{0, 1\}$$

a function that evaluates if a given state is the goal or not.

Sometimes the set of goals $g^{-1}(1)$ is enumerated explicitely, e.g., $g^{-1}(1) = \{\text{In(Bucharest)}\}.$

path costs:
$$c: (A \times X)^* \to \mathbb{R}$$

the cost of performing the sequence of actions a_1, a_2, \ldots, a_n to move from x_0 to x_1 , from x_1 to x_2 , etc., and finally from x_{n-1} to x_n .

Path costs often are assumed to be just the sum of single step costs:

$$c(a_1, x_1, a_2, x_2, \dots, a_n, x_n) = \sum_{i=1}^n c_{\mathsf{step}}(x_{i-1}, a_i, x_i)$$

Problems / State graph

Problems can be represented as directed graphs with labeled edges:

vertices: states X.

edges: there is an edge from vertex x to x' if there is an action a with succ(x, a) = x'.

edge labels: edges are labeled twofold:

- with the action a and
- with the step costs c(x, a, x').

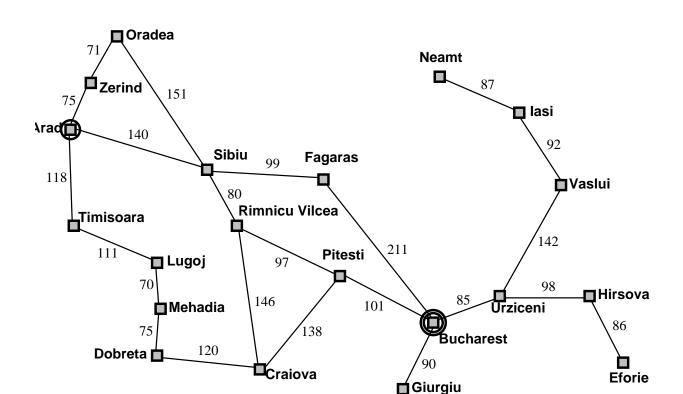

If from each state each successor state can be reached by at most one action, the action label often is omitted (as it is fully determined by the two states).

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

12/44

Artificial Intelligence / 2. Problem Descriptions

Problems / State graph / Example

Solutions

A path in the state space can be described either by a sequence

$$(a_1, x_1, a_2, x_2, \dots, a_n, x_n) \in (A \times X)^*, \text{ with } succ}(x_{i-1}, a_i) = x_i, i = 1, \dots, n$$

or equivalently by a pure action sequence

$$(a_1, a_2, \dots, a_n) \in A^*$$

where

$$x_i := succ(x_{i-1}, a_i), \quad i = 1, \dots, n$$

A **solution** is a path that reaches the goal, i.e., with $g(x_n) = 1$.

An **optimal solution** is a solution with smallest cost $c(a_1, x_1, a_2, x_2, \dots, a_n, x_n)$ among all solutions.

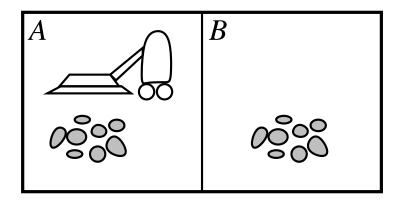

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

14/44

Artificial Intelligence / 2. Problem Descriptions

Examples / Vacuum cleaner

state space $X:=\{A,B\}\times\{\text{dirty},\text{clean}\}^{\{A,B\}},\quad |X|=8.$ initial state any.

successor function

 $\operatorname{succ}((A,\{(A,\operatorname{dirty}),(B,\operatorname{dirty})\}),\operatorname{suck})=(A,\{(A,\operatorname{clean}),(B,\operatorname{dirty})\})$ etc. (see next slide).

goal function: $g((*, \{(A, \mathsf{clean}), (B, \mathsf{clean})\})) = 1$, else 0.

path cost: c(x, a, x') = 1

Examples / Vacuum cleaner

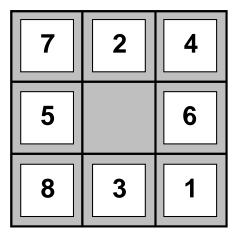

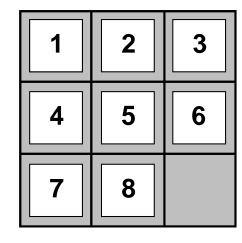

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

Artificial Intelligence / 2. Problem Descriptions

16/44

Examples / 8-puzzle

Start State

Goal State

state space $X := \{f : \{1, 2, \dots, 8\} \rightarrow \{1, 2, \dots, 9\} \mid f \text{ injective}\}.$ initial state any.

successor function effect of moving the blank (see next slide).

goal function: g(designated goal state) = 1, else 0.

path cost: c(x, a, x') = 1

Examples / 8-puzzle

$$\mathbf{succ}(\begin{pmatrix} 7 & 2 & 4 \\ 5 & 6 \\ 8 & 3 & 1 \end{pmatrix}, \mathbf{move\ blank\ left}) = \begin{pmatrix} 7 & 2 & 4 \\ 5 & 6 \\ 8 & 3 & 1 \end{pmatrix}$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

18/44

Artificial Intelligence / 2. Problem Descriptions

Examples / 8-puzzle

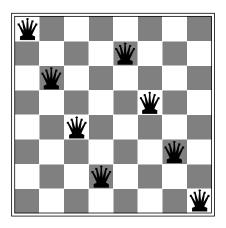

8-puzzle is an instance of the **sliding-block puzzle** class, a NP-complete problem class.

name	board	reachable states	difficulty
8-puzzle	3×3	9!/2 = 181,440	solved easily
15-puzzle	4×4	$\approx 1.3 \cdot 10^{18}$	solved in a few milliseconds
24-puzzle	5×5	$\approx 10^{25}$	difficult to solve

Examples / 8-queens problem

state space

$$X := \{x \subset \{1, \dots, 64\} \mid |x| \le 8\}, \quad |X| = \binom{64}{8} = 4.4 \cdot 10^9$$

initial state $x = \emptyset$.

successor function add a queen to any empty square.

goal function: goal reached if 8 queens on the board, none attacked.

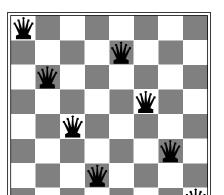

path cost: c(x, a, x') = 1

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

20/44

Artificial Intelligence / 2. Problem Descriptions

Examples / 8-queens problem

A better problem formulation:

state space n queens ($n=0,\ldots,8$) in the n left-most columns, one per column, non attacked. |X|=2057.

initial state $x = \emptyset$.

successor function add a queen to the left-most empty column, not attacked.

goal function: goal reached if 8 queens on the board, none attacked.

path cost: c(x, a, x') = 1

- 1. The Agent Metaphor
- 2. Problem Descriptions
- 3. Uninformed Tree Search
- 4. Uninformed Graph Search

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

Artificial Intelligence / 3. Uninformed Tree Search

The Problem (1/3)

Algorithmics / Graph theory:

Given a directed graph G:=(V,E) with edge weights $w:E\to\mathbb{R}$ and two vertices $x,y\in V$, find a shortest path from x to y, i.e., a path $P\in V^*$ with $P_1=x,P_2=y$ and

$$w(P) := \sum_{i=1}^{n-1} w(P_i, P_{i+1})$$

minimal among all paths from x to y.

Artificial Intelligence:

If from each state any other state can be reached by at most one action and costs decompose in single step costs, then

$$\begin{split} V := & X \quad \text{(the states)} \\ E := & \{(x,y) \in X^2 \,|\, \exists a \in A : \mathsf{succ}(x,a) = y\} \\ w(x,y) := & \mathsf{cost}(x,a,y) \quad (a \text{ unique with } \mathsf{succ}(x,a) = y) \\ x := & x_0 \quad \text{(initial state)} \\ y := & \mathsf{any} \,\, x \in X \,\, \mathsf{with} \,\, g(x) = 1 \end{split}$$

The Problem (2/3)

But:

- *X* often is not finite, so it cannot be stored, but relevant portions must be constructed by succ recursively.
- $g^{-1}(1)$ may not be easy to compute (although for each specific x it may be easy to check if g(x) = 1, e.g., check-mate).

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

23/44

Artificial Intelligence / 3. Uninformed Tree Search

The Problem (3/3)

Each state can be reached by at most one sequence of actions.

I.e., the search space is a tree.

Breadth-First Search

Idea:

- start with initial state as border.
- iteratively replace border by all states reachable from the old border.

```
\begin{array}{ll} \textit{1} \; \text{breadth-first-search}(X, \text{succ}, \text{border}, g): \\ \textit{2} \; \text{newborder} := \emptyset \\ \textit{3} \; \underline{\textbf{for}} \; x \in \text{border} \; \underline{\textbf{do}} \\ \textit{4} \; & \underline{\textbf{for}} \; y \in \text{succ}(x, A) \; \underline{\textbf{do}} \\ \textit{5} \; & \underline{\textbf{if}} \; g(y) = 1 \\ \textit{6} \; & \underline{\textbf{return}} \; y \\ \textit{7} \; & \underline{\textbf{else}} \\ \textit{8} \; & \text{newborder} := \text{newborder} \cup \{y\} \\ \textit{9} \; & \underline{\textbf{fi}} \\ \textit{10} \; & \underline{\textbf{od}} \\ \textit{11} \; & \underline{\textbf{od}} \\ \textit{12} \; & \underline{\textbf{if}} \; \text{newborder} \neq \emptyset \\ \textit{13} \; & \underline{\textbf{return}} \; \text{breadth-first-search}(X, \text{succ}, \text{newborder}, g) \\ \textit{14} \; & \underline{\textbf{else}} \\ \textit{15} \; & \underline{\textbf{return}} \; \emptyset \\ \textit{16} \; & \underline{\textbf{fi}} \end{array}
```

Artificial Intelligence / 3. Uninformed Tree Search

Characteristics of Algorithms

In algorithmics, the complexity of (shortest path) algorithms is measured in steps as function of the number of vertices and edges (big-O notation).

For problems with infinite number of vertices or edges this is not possible.

Use instead:

maximum branching factor b:

maximum number of successors of a state.

depth of least-cost solution d:

length of least cost path to a goal state.

maximum depth of state space m

length of longest path, also called diameter; evtl. ∞ .

Characteristics of Algorithms

Characterize by:

Completeness

does the algorithm always find a solution if one exists?

Optimality

does the algorithm always find an optimal solution?

Time complexity

size of the visited part of the search tree

Space complexity

size of the search tree in memory

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

Artificial Intelligence / 3. Uninformed Tree Search

Completeness

yes (if b is finite)

Optimality

no (unless all step costs are the same, e.g., 1)

Time complexity

$$1 + b + b^{2} + \dots + b^{d} + b(b^{d} - 1) = O(b^{d+1})$$

Space complexity

same as time complexity as whole search tree is kept in memory.

Uniform Cost Search

Idea:

- as breadth-first search.
- but visit state with minimal path cost first.

```
i uniform-cost-search(X, succ, cost, x_0, g):
 2 border := \{x_0\}
 s \ c(x_0) := 0
    while border \neq \emptyset do
              x := \mathrm{argmin}_{x \in \mathrm{border}} c(x)
              \underline{\mathbf{if}} g(x) = 1
                  \underline{\mathbf{return}} \ x
              \underline{\mathbf{for}} \ y \in \operatorname{succ}(x, A) \ \underline{\mathbf{do}}
                     border := border \cup \{y\}
                    c(y) := c(x) + \cot(x, y)
11
12
               border := border \setminus \{x\}
13
14 od
15 return ∅
```

Artificial Intelligence / 3. Uninformed Tree Search

Iterative Deepening Search

Idea:

- as depth-limited search.
- but repeat for increasing maximal depth maxdepth.

```
 \begin{array}{ll} \textit{1} & \text{iterative-deepening-search}(X, \text{succ}, x_0, g, \text{maxdepth}): \\ \textit{2} & \underline{\textbf{for}} \ d = 1 \dots \text{maxdepth} \ \underline{\textbf{do}} \\ \textit{3} & P := \text{depth-limited-search}(X, \text{succ}, x_0, g, d); \\ \textit{4} & \underline{\textbf{if}} \ P \neq \text{``cutoff''} \\ \textit{5} & \underline{\textbf{return}} \ P \\ \textit{6} & \underline{\textbf{fi}} \\ \textit{7} & \underline{\textbf{od}} \\ \textit{8} & \underline{\textbf{return}} \text{``cutoff''} \end{array}
```

Iterative Deepening Search

Completeness

yes

Optimality

no (unless all step costs are equal, e.g., 1; but can be modified).

Time complexity

$$O((d+1) + db + (d-1)b^2 + \dots + b^d) = O(b^d)$$

Space complexity

O(bd)

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany, Course on Artificial Intelligence, summer term 2007

Uniform Cost Search / Explicit branch bookkeeping

```
1 uniform-cost-search(X, succ, cost, x_0, g):
 2 border := \{x_0\}
s c(x_0) := 0
    while border \neq \emptyset do
               x := \mathrm{argmin}_{x \in \mathrm{border}} c(x)
              \underline{\mathbf{if}} g(x) = 1
                  \underline{\mathbf{return}} \ x
8
              \underline{\mathbf{for}} \ y \in \operatorname{succ}(x, A) \ \underline{\mathbf{do}}
                     border := border \cup \{y\}
10
                     c(y) := c(x) + \cot(x, y)
11
              border := border \setminus \{x\}
13
14 <u>od</u>
15 return Ø
```

If succ is expensive to invert (or not possible to invert, because the search space is not a tree), branches must be stored explicitely.

```
i uniform-cost-search(X, succ, cost, x_0, g):
 2 border := \{x_0\}
 c(x_0) := 0
    while border \neq \emptyset do
             x := \mathrm{argmin}_{x \in \mathrm{border}} c(x)
             \underline{\mathbf{if}} g(x) = 1
                return branch(x)
             \underline{\mathbf{for}}\ y \in \mathrm{succ}(x,A)\ \underline{\mathbf{do}}
                  border := border \cup \{y\}
10
                  c(y) := c(x) + \cot(x, y)
11
                  previous(y) := x
13
             <u>od</u>
             border := border \setminus \{x\}
15 <u>od</u>
16 <u>return</u> ∅
18 branch(x, previous):
19 P := \emptyset
    <u>while</u> previous(x)! = \emptyset <u>do</u>
             insert-at-beginning(P, x)
             x := \operatorname{previous}(x)
22
23 od
24 return P
```

Artificial Intelligence / 4. Uninformed Graph Search

Uniform Cost Search / Duplicate states

If duplicate states can occur
(i.e., there are several paths to the same state,
i.e., the search space is not a tree),
and if still a tree search should be applied,
states cannot be used as index anymore,
but have to be wrapped in "nodes".

The same modifications have to be applied to all other search algorithms.

Uniform Cost Search / Duplicate states

```
i uniform-cost-search(X, succ, cost, x_0, g):
                                                                                       i uniform-cost-search(X, succ, cost, x_0, g):
 2 border := \{x_0\}
                                                                                       2 N := \text{new node}(\text{state} = x_0, c = 0, \text{previous} = \emptyset)

Artificial Intelligence / 4. Uninformed Graph Search

Several paths blow up the search tree

Closed list

The tree search algorithms must be modified s.t. they keep track of all the nodes visited so far (so-called **closed list**).

If the current state is already in the closed list, it is discarded instead of expanded.

This means that all algorithms have to keep the whole visited part of the state space in memory, i.e., the space complexity always is the one of breadth first search..
