Machine Learning

1. Linear Regression

Lars Schmidt-Thieme

Information Systems and Machine Learning Lab (ISMLL)
Institute for Business Economics and Information Systems
& Institute for Computer Science
University of Hildesheim
http://www.ismll.uni-hildesheim.de

Example

Example: how does gas consumption depend on external temperature? (Whiteside, 1960s).
weekly measurements of
- average external temperature
- total gas consumption
  (in 1000 cubic feets)
A third variable encodes two heating seasons, before and after wall insulation.

How does gas consumption depend on external temperature?

How much gas is needed for a given temperature ?

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
1/70

Example

linear model

Example

linear model

more flexible model

Variable Types and Coding

The most common variable types:

numerical / **interval-scaled** / **quantitative**
where differences and quotients etc. are meaningful,
usually with domain $\mathcal{X} := \mathbb{R}$,
e.g., temperature, size, weight.

nominal / **discrete** / **categorical** / **qualitative** / **factor**
where differences and quotients are not defined,
usually with a finite, enumerated domain,
e.g., $\mathcal{X} := \{\text{red}, \text{green}, \text{blue}\}$
or $\mathcal{X} := \{\text{a}, \text{b}, \text{c}, \ldots, \text{y}, \text{z}\}$.

ordinal / **ordered categorical**
where levels are ordered, but differences and quotients are not
defined,
usually with a finite, enumerated domain,
e.g., $\mathcal{X} := \{\text{small}, \text{medium}, \text{large}\}$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
4/70

Variable Types and Coding

Nominals are usually encoded as binary **dummy variables**:

$$\delta_{x_0}(X) := \begin{cases} 1, & \text{if } X = x_0, \\ 0, & \text{else} \end{cases}$$

one for each $x_0 \in \mathcal{X}$ (but one).

Example: $\mathcal{X} := \{\text{red}, \text{green}, \text{blue}\}$

Replace

       one variable X with 3 levels: red, green, blue

by

   two variables $\delta_{\text{red}}(X)$ and $\delta_{\text{green}}(X)$ with 2 levels each: 0, 1

X	$\delta_{\text{red}}(X)$	$\delta_{\text{green}}(X)$
red	1	0
green	0	1
blue	0	0
—	1	1

Course on Machine Learning, winter term 2011/12
5/70

The Regression Problem Formally

Let

$X_1, X_2, \ldots, X_p$ be random variables called **predictors** (or **inputs**, **covariates**).
Let $\mathcal{X}_1, \mathcal{X}_2, \ldots, \mathcal{X}_p$ be their domains.
We write shortly

$$X := (X_1, X_2, \ldots, X_p)$$

for the vector of random predictor variables and

$$\mathcal{X} := \mathcal{X}_1 \times \mathcal{X}_2 \times \cdots \times \mathcal{X}_p$$

for its domain.

Y be a random variable called **target** (or **output**, **response**).
Let $\mathcal{Y}$ be its domain.

$\mathcal{D} \subseteq \mathcal{X} \times \mathcal{Y}$ be a (multi)set of instances of the unknown joint distribution $p(X, Y)$ of predictors and target called **data**.
$\mathcal{D}$ is often written as enumeration

$$\mathcal{D} = \{(x_1, y_1), (x_2, y_2), \ldots, (x_n, y_n)\}$$

The Regression Problem Formally

The task of regression and classification is
to predict Y based on X,
i.e., to estimate

$$r(x) := E(Y \mid X = x) = \int y \, p(y|x) dy$$

based on data (called **regression function**).

If Y is numerical, the task is called **regression**.

If Y is nominal, the task is called **classification**.

Course on Machine Learning, winter term 2011/12
13/70

Simple Linear Regression Model

Make it simple:

- the predictor X is simple, i.e., one-dimensional ($X = X_1$).

- $r(x)$ is assumed to be linear:

$$r(x) = \beta_0 + \beta_1 x$$

- assume that the variance does not depend on X:

$$Y = \beta_0 + \beta_1 X + \epsilon, \quad E(\epsilon|X) = 0, V(\epsilon|X) = \sigma^2$$

- 3 parameters:
  β_0 **intercept** (sometimes also called bias)
  β_1 **slope**
  σ^2 **variance**

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
14/70

Simple Linear Regression Model

parameter estimates

$$\hat{\beta}_0, \hat{\beta}_1, \hat{\sigma}^2$$

fitted line

$$\hat{r}(x) := \hat{\beta}_0 + \hat{\beta}_1 x$$

predicted / fitted values

$$\hat{y}_i := \hat{r}(x_i)$$

residuals

$$\hat{\epsilon}_i := y_i - \hat{y}_i = y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i)$$

residual sums of squares (RSS) / square loss / L2 loss

$$\text{RSS} = \sum_{i=1}^{n} \hat{\epsilon}_i^2$$

18/70
Least Squares Estimates / Definition

In principle, there are many different methods to estimate the parameters $\hat{\beta}_0, \hat{\beta}_1$ and $\hat{\sigma}^2$ from data — depending on the properties the solution should have.

The **least squares estimates** are those parameters that minimize

$$\text{RSS} = \sum_{i=1}^{n} \hat{\epsilon}_i^2 = \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 = \sum_{i=1}^{n} (y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i))^2$$

They can be written in closed form as follows:

$$\hat{\beta}_1 = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^{n}(x_i - \bar{x})^2}$$

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$

$$\hat{\sigma}^2 = \frac{1}{n-2} \sum_{i=1}^{n} \hat{\epsilon}_i^2$$

Least Squares Estimates / Proof

Proof (1/2):

$$\text{RSS} = \sum_{i=1}^{n} (y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i))^2$$

$$\frac{\partial \text{RSS}}{\partial \hat{\beta}_0} = \sum_{i=1}^{n} 2(y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i))(-1) \overset{!}{=} 0$$

$$\implies \quad n\hat{\beta}_0 = \sum_{i=1}^{n} (y_i - \hat{\beta}_1 x_i)$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
20/70

Least Squares Estimates / Proof

Proof (2/2):

$$
\text{RSS} = \sum_{i=1}^{n} (y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i))^2
$$

$$
= \sum_{i=1}^{n} (y_i - (\bar{y} - \hat{\beta}_1 \bar{x}) - \hat{\beta}_1 x_i)^2
$$

$$
= \sum_{i=1}^{n} (y_i - \bar{y} - \hat{\beta}_1 (x_i - \bar{x}))^2
$$

$$
\frac{\partial \text{RSS}}{\partial \hat{\beta}_1} = \sum_{i=1}^{n} 2(y_i - \bar{y} - \hat{\beta}_1 (x_i - \bar{x}))(-1)(x_i - \bar{x}) \stackrel{!}{=} 0
$$

$$
\implies \quad \hat{\beta}_1 = \frac{\sum_{i=1}^{n} (y_i - \bar{y})(x_i - \bar{x})}{\sum_{i=1}^{n} (x_i - \bar{x})^2}
$$

Least Squares Estimates / Example

Example:

Given the data $\mathcal{D} := \{(1,2), (2,3), (4,6)\}$, predict a value for $x = 3$.
Assume simple linear model.

$\bar{x} = 7/3$, $\bar{y} = 11/3$.

i	$x_i - \bar{x}$	$y_i - \bar{y}$	$(x_i - \bar{x})^2$	$(x_i - \bar{x})(y_i - \bar{y})$
1	$-4/3$	$-5/3$	$16/9$	$20/9$
2	$-1/3$	$-2/3$	$1/9$	$2/9$
3	$5/3$	$7/3$	$25/9$	$35/9$
$\sum$			$42/9$	$57/9$

$$\hat{\beta}_1 = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^{n}(x_i - \bar{x})^2} = 57/42 = 1.357$$
$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1\bar{x} = \frac{11}{3} - \frac{57}{42} \cdot \frac{7}{3} = \frac{63}{126} = 0.5$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
22/70

Least Squares Estimates / Example

Example:

Given the data $\mathcal{D} := \{(1,2), (2,3), (4,6)\}$, predict a value for $x = 3$.
Assume simple linear model.

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2} = 57/42 = 1.357$$

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x} = \frac{11}{3} - \frac{57}{42} \cdot \frac{7}{3} = \frac{63}{126} = 0.5$$

RSS:

i	y_i	$\hat{y}_i$	$(y_i - \hat{y}_i)^2$
1	2	1.857	0.020
2	3	3.214	0.046

23/70
A Generative Model

So far we assumed the model

$$Y = \beta_0 + \beta_1 X + \epsilon, \quad E(\epsilon|X) = 0, V(\epsilon|X) = \sigma^2$$

where we required some properties of the errors,
but not its exact distribution.

If we make assumptions about its distribution, e.g.,

$$\epsilon|X \sim \mathcal{N}(0, \sigma^2)$$

and thus

$$Y|X = x \sim \mathcal{N}(\beta_0 + \beta_1 x, \sigma^2)$$

we can sample from this model.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
24/70

Maximum Likelihood Estimates (MLE)

Let $p(X, Y \mid \theta)$ be a joint probability density function for X and Y with parameters θ.

Likelihood:

$$L_{\mathcal{D}}(\theta) := \prod_{i=1}^{n} p(x_i, y_i \mid \theta)$$

The likelihood describes the probability of the data.

The **maximum likelihood estimates (MLE)** are those parameters that maximize the likelihood.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
25/70

Least Squares Estimates and Maximum Likelihood Estimates

Likelihood:

$$L_{\mathcal{D}}(\hat{\beta}_0, \hat{\beta}_1, \hat{\sigma}^2) := \prod_{i=1}^{n} \hat{p}(x_i, y_i) = \prod_{i=1}^{n} \hat{p}(y_i \mid x_i) p(x_i) = \prod_{i=1}^{n} \hat{p}(y_i \mid x_i) \prod_{i=1}^{n} p(x_i)$$

Conditional likelihood:

$$L_{\mathcal{D}}^{\text{cond}}(\hat{\beta}_0, \hat{\beta}_1, \hat{\sigma}^2) := \prod_{i=1}^{n} \hat{p}(y_i \mid x_i) = \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi}\hat{\sigma}} e^{-\frac{(y_i - \hat{y}_i)^2}{2\hat{\sigma}^2}} = \frac{1}{\sqrt{2\pi}^n \hat{\sigma}^n} e^{\frac{1}{-2\hat{\sigma}^2} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2}$$

Conditional log-likelihood:

$$\log L_{\mathcal{D}}^{\text{cond}}(\hat{\beta}_0, \hat{\beta}_1, \hat{\sigma}^2) \propto -n \log \hat{\sigma} - \frac{1}{2\hat{\sigma}^2} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

$\implies$ if we assume normality, the maximum likelihood estimates are just the least squares estimates.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
26/70

Implementation Details

(1) $\text{simple-regression}(\mathcal{D})$:

(2) $\text{sx} := 0, \text{sy} := 0$

(3) for $i = 1, \ldots, n$ do

(4) $\quad \text{sx} := \text{sx} + x_i$

(5) $\quad \text{sy} := \text{sy} + y_i$

(6) od

(7) $\bar{x} := \text{sx}/n, \bar{y} := \text{sy}/n$

(8) $a := 0, b := 0$

(9) for $i = 1, \ldots, n$ do

(10) $\quad a := a + (x_i - \bar{x})(y_i - \bar{y})$

(11) $\quad b := b + (x_i - \bar{x})^2$

(12) od

(13) $\beta_1 := a/b$

(14) $\beta_0 := \bar{y} - \beta_1 \bar{x}$

(15) return (β_0, β_1)

Implementation Details

naive:

(1) simple-regression($\mathcal{D}$) :

(2) sx := 0, sy := 0

(3) **for** $i = 1, \ldots, n$ **do**

(4)   sx := sx + x_i

(5)   sy := sy + y_i

(6) **od**

(7) $\bar{x} := $ sx$/n, \bar{y} := $ sy$/n$

(8) $a := 0, b := 0$

(9) **for** $i = 1, \ldots, n$ **do**

(10) $a := a + (x_i - \bar{x})(y_i - \bar{y})$

(11) $b := b + (x_i - \bar{x})^2$

(12) **od**

(13) $\beta_1 := a/b$

(14) $\beta_0 := \bar{y} - \beta_1 \bar{x}$

(15) **return** (β_0, β_1)

single loop:

1 simple-regression($\mathcal{D}$) :

2 sx := 0, sy := 0, sxx := 0, syy := 0, sxy := 0

3 **for** $i = 1, \ldots, n$ **do**

4   sx := sx + x_i

5   sy := sy + y_i

6   sxx := sxx + x_i^2

7   syy := syy + y_i^2

8   sxy := sxy + $x_i y_i$

9 **od**

10 $\beta_1 := (n \cdot sxy - sx \cdot sy)/(n \cdot sxx - sx \cdot sx)$

11 $\beta_0 := ($sy$ - \beta_1 \cdot sx)/n$

12 **return** (β_0, β_1)

Several predictors

Several predictor variables $X_1, X_2, \ldots, X_p$:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \cdots \beta_P X_P + \epsilon$$

$$= \beta_0 + \sum_{i=1}^{p} \beta_i X_i + \epsilon$$

with $p + 1$ parameters $\beta_0, \beta_1, \ldots, \beta_p$.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
28/70

Linear form

Several predictor variables $X_1, X_2, \ldots, X_p$:

$$Y = \beta_0 + \sum_{i=1}^{p} \beta_i X_i + \epsilon$$
$$= \langle \beta, X \rangle + \epsilon$$

where

$$\beta := \begin{pmatrix} \beta_0 \\ \beta_1 \\ \vdots \\ \beta_p \end{pmatrix}, \quad X := \begin{pmatrix} 1 \\ X_1 \\ \vdots \\ X_p \end{pmatrix},$$

Thus, the intercept is handled like any other parameter, for the artificial constant variable $X_0 \equiv 1$.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
29/70

Simultaneous equations for the whole dataset

For the whole dataset $(x_1, y_1), \ldots, (x_n, y_n)$:

$$\mathbf{Y} = \mathbf{X}\beta + \epsilon$$

where

$$\mathbf{Y} := \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix}, \quad \mathbf{X} := \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} x_{1,1} & x_{1,2} & \ldots & x_{1,p} \\ \vdots & \vdots & \vdots & \vdots \\ x_{n,1} & x_{n,2} & \ldots & x_{n,p} \end{pmatrix}, \quad \epsilon := \begin{pmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{pmatrix},$$

Least squares estimates

Least squares estimates $\hat{\beta}$ minimize

$$||\mathbf{Y} - \hat{\mathbf{Y}}||^2 = ||\mathbf{Y} - \mathbf{X}\hat{\beta}||^2$$

The least squares estimates $\hat{\beta}$ are computed via

$$\mathbf{X}^T\mathbf{X}\hat{\beta} = \mathbf{X}^T\mathbf{Y}$$

Proof:

$$||\mathbf{Y} - \mathbf{X}\hat{\beta}||^2 = \langle \mathbf{Y} - \mathbf{X}\hat{\beta}, \mathbf{Y} - \mathbf{X}\hat{\beta} \rangle$$

$$\frac{\partial(\ldots)}{\partial\hat{\beta}} = 2\langle -\mathbf{X}, \mathbf{Y} - \mathbf{X}\hat{\beta} \rangle = -2(\mathbf{X}^T\mathbf{Y} - \mathbf{X}^T\mathbf{X}\hat{\beta}) \stackrel{!}{=} 0$$

How to compute least squares estimates $\hat{\beta}$

Solve the $p \times p$ system of linear equations

$$\mathbf{X}^T \mathbf{X} \hat{\beta} = \mathbf{X}^T \mathbf{Y}$$

i.e., $Ax = b$ (with $A := \mathbf{X}^T\mathbf{X}, b = \mathbf{X}^T\mathbf{Y}, x = \hat{\beta}$).

There are several numerical methods available:

1. Gaussian elimination

2. Cholesky decomposition

3. QR decomposition

Course on Machine Learning, winter term 2011/12
38/70
The Normal Distribution (also Gaussian)

written as:

$$X \sim \mathcal{N}(\mu, \sigma^2)$$

with parameters:
μ mean,
σ standard deviance.

probability density function (pdf):

$$\phi(x) := \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

cumulative distribution function (cdf):

$$\Phi(x) := \int_{-\infty}^{x} \phi(t)dt$$

Φ^{-1} is called **quantile function**.

Φ and Φ^{-1} have no analytical form, but have to be computed numerically.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
39/70
The t Distribution

written as:

$$X \sim t_p$$

with parameter:
p degrees of freedom.

probability density function (pdf):

$$p(x) := \frac{\Gamma(\frac{p+1}{2})}{\sqrt{p\,\pi}\,\Gamma(\frac{p}{2})}(1 + \frac{x^2}{p})^{-\frac{p+1}{2}}$$

$$t_p \xrightarrow{p \to \infty} \mathcal{N}(0,1)$$
The χ^2 Distribution

written as:

$$X \sim \chi_p^2$$

with parameter:

p degrees of freedom.

probability density function (pdf):

$$p(x) := \frac{1}{\Gamma(p/2)2^{p/2}} x^{\frac{p}{2}-1} e^{-\frac{x}{2}}, \quad x \geq 0$$

If $X_1, \ldots, X_p \sim \mathcal{N}(0,1)$, then

$$Y := \sum_{i=1}^{p} X_i^2 \sim \chi_p^2$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
41/70
Parameter Variance

$\hat{\beta} = (\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\mathbf{Y}$ is an unbiased estimator for β (i.e., $E(\hat{\beta}) = \beta$). Its variance is

$$V(\hat{\beta}) = (\mathbf{X}^T\mathbf{X})^{-1}\sigma^2$$

proof:

$$\hat{\beta} = (\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\mathbf{Y} = (\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T(\mathbf{X}\beta + \epsilon) = \beta + (\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\epsilon$$

As $E(\epsilon) = 0$: $E(\hat{\beta}) = \beta$

$$\begin{aligned}
V(\hat{\beta}) =& E((\hat{\beta} - E(\hat{\beta}))(\hat{\beta} - E(\hat{\beta}))^T) \\
=& E((\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\epsilon\epsilon^T\mathbf{X}(\mathbf{X}^T\mathbf{X})^{-1}) \\
=& (\mathbf{X}^T\mathbf{X})^{-1}\sigma^2
\end{aligned}$$

Parameter Variance

An unbiased estimator for σ^2 is

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_{i=1}^{n} \hat{\epsilon}_i^2 = \frac{1}{n-p} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

If $\epsilon \sim \mathcal{N}(0, \sigma^2)$, then

$$\hat{\beta} \sim \mathcal{N}(\beta, (\mathbf{X}^T\mathbf{X})^{-1}\sigma^2)$$

Furthermore

$$(n-p)\hat{\sigma}^2 \sim \sigma^2 \chi_{n-p}^2$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
43/70

Parameter Variance / Standardized coefficient

standardized coefficient ("z-score"):

$$z_i := \frac{\hat{\beta}_i}{\widehat{\text{se}}(\hat{\beta}_i)}, \quad \text{with } \widehat{\text{se}}^2(\hat{\beta}_i) \text{ the } i\text{-th diagonal element of } (\mathbf{X}^T\mathbf{X})^{-1}\hat{\sigma}^2$$

z_i would be $z_i \sim \mathcal{N}(0,1)$ if σ is known (under $H_0 : \beta_i = 0$).
With estimated $\hat{\sigma}$ it is $z_i \sim t_{n-p}$.

The Wald test for $H_0 : \beta_i = 0$ with size α is:

$$\text{reject } H_0 \text{ if } |z_i| = |\frac{\hat{\beta}_i}{\widehat{\text{se}}(\hat{\beta}_i)}| > F^{-1}_{t_{n-p}}(1 - \frac{\alpha}{2})$$

i.e., its p-value is

$$p\text{-value}(H_0 : \beta_i = 0) = 2(1 - F_{t_{n-p}}(|z_i|)) = 2(1 - F_{t_{n-p}}(|\frac{\hat{\beta}_i}{\widehat{\text{se}}(\hat{\beta}_i)}|))$$

and small p-values such as 0.01 and 0.05 are good.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
44/70

Parameter Variance / Confidence interval

The $1 - \alpha$ confidence interval for β_i:

$$\beta_i \pm F_{t_{n-p}}^{-1}(1 - \frac{\alpha}{2})\widehat{\text{se}}(\hat{\beta}_i)$$

For large n, $F_{t_{n-p}}$ converges to the standard normal cdf Φ.

As $\Phi^{-1}(1 - \frac{0.05}{2}) \approx 1.95996 \approx 2$, the rule-of-thumb for a 5% confidence interval is

$$\beta_i \pm 2\widehat{\text{se}}(\hat{\beta}_i)$$

Parameter Variance / Example

We have already fitted   to the data:

x_1	x_2	y	$\hat{y}$	$\hat{\epsilon}^2 = (y - \hat{y})^2$

Parameter Variance / Example 2

Example: sociographic data of the 50
US states in 1977.

state dataset:

- income (per capita, 1974),

- illiteracy (percent of population,
  1970),

- life expectancy (in years, 1969–71),

- percent high-school graduates
  (1970).

- population (July 1, 1975)

- murder rate per 100,000 population
  (1976)

- mean number of days with minimum
  temperature below freezing
  (1931–1960) in capital or large city

- land area in square miles

Need for higher orders

Assume a target variable does not
depend linearly on a predictor variable,
but say quadratic.

Example: way length vs. duration of a
moving object with constant
acceleration a.

$$s(t) = \frac{1}{2}at^2 + \epsilon$$

Can we catch such a dependency?

Can we catch it with a linear model?

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
49/70
Need for general transformations

To describe many phenomena, even more complex functions of the input variables are needed.

Example: the number of cells n vs. duration of growth t:

$$n = \beta e^{\alpha t} + \epsilon$$

n does not depend on t directly, but on $e^{\alpha t}$ (with a known α).

Need for variable interactions

In a linear model with two predictors

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon$$

Y depends on both, X_1 and X_2.

But changes in X_1 will affect Y the same way, regardless of X_2.

There are problems where X_2 mediates or influences the way X_1 affects Y, e.g. : the way length s of a moving object vs. its constant velocity v and duration t:

$$s = vt + \epsilon$$

Then an additional $1s$ duration will increase the way length not in a uniform way (regardless of the velocity), but a little for small velocities and a lot for large velocities.

v and t are said to interact: y does not depend only on each predictor separately, but also on their product.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
51/70

Derived variables

All these cases can be handled by looking at **derived variables**, i.e., instead of

$$Y = \beta_0 + \beta_1 X_1^2 + \epsilon$$
$$Y = \beta_0 + \beta_1 e^{\alpha X_1} + \epsilon$$
$$Y = \beta_0 + \beta_1 X_1 \cdot X_2 + \epsilon$$

one looks at

$$Y = \beta_0 + \beta_1 X_1' + \epsilon$$

with

$$X_1' := X_1^2$$
$$X_1' := e^{\alpha X_1}$$
$$X_1' := X_1 \cdot X_2$$

Derived variables are computed before the fitting process and taken into account either additional to the original variables or instead of.

Course on Machine Learning, winter term 2011/12
52/70
Underfitting

If a model does not well explain the data,
e.g., if the true model is quadratic, but we try to fit a linear model,
one says, the model **underfits**.

Course on Machine Learning, winter term 2011/12
54/70

Overfitting / Fitting Polynomials of High Degree

If to data

$$(x_1, y_1), (x_2, y_2), \ldots, (x_n, y_n)$$

consisting of n points we fit

$$X = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \cdots + \beta_{n-1} X_{n-1}$$

i.e., a polynomial with degree $n - 1$, then this results in an interpolation of the data points
(if there are no repeated measurements, i.e., points with the same X_1.)

As the polynomial

$$r(X) = \sum_{i=1}^{n} y_i \prod_{j \neq i} \frac{X - x_j}{x_i - x_j}$$

is of this type, and has minimal RSS $= 0$.

Course on Machine Learning, winter term 2011/12
54/70

Model Selection Measures

Model selection means: we have a set of models, e.g.,

$$Y = \sum_{i=0}^{p-1} \beta_i X_i$$

indexed by p (i.e., one model for each value of p),
make a choice which model **describes** the data best.

If we just look at **losses** / **fit measures** such as RSS, then

the larger p, the better the fit

or equivalently

the larger p, the lower the loss

as the model with p parameters can be **reparametrized** in a
model with $p' > p$ parameters by setting

$$\beta_i' = \begin{cases} \beta_i, & \text{for } i \le p \\ 0, & \text{for } i > p \end{cases}$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
55/70

Model Selection Measures

One uses **model selection measures** of type

$$\text{model selection measure} = \text{fit} - \text{complexity}$$

or equivalently

$$\text{model selection measure} = \text{loss} + \text{complexity}$$

The smaller the loss (= lack of fit), the better the model.

The smaller the complexity, the simpler and thus better the model.

The model selection measure tries to find a trade-off between fit/loss and complexity.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
56/70

Model Selection Measures

Akaike Information Criterion (AIC): (maximize)

$$\text{AIC} := \log L - p$$

or (minimize)

$$\text{AIC} := -2 \log L + 2p = -2n \log(\text{RSS}/n) + 2p$$

Bayes Information Criterion (BIC) /
Bayes-Schwarz Information Criterion: (maximize)

$$\text{BIC} := \log L - \frac{p}{2} \log n$$

59/70

Shrinkage

Model selection operates by

- fitting models for a set of models with varying complexity and then picking the "best one" ex post,

- omitting some parameters completely (i.e., forcing them to be 0)

shrinkage operates by

- including a penalty term directly in the model equation and

- favoring small parameter values in general.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
60/70

Shrinkage / Ridge Regression [**?**]

Ridge regression: minimize

$$\text{RSS}_\lambda(\hat{\beta}) = \text{RSS}(\hat{\beta}) + \lambda \sum_{j=1}^{p} \hat{\beta}_j^2$$

$$= \langle \mathbf{y} - \mathbf{X}\hat{\beta}, \mathbf{y} - \mathbf{X}\hat{\beta} \rangle + \lambda \sum_{j=1}^{p} \hat{\beta}_j^2$$

$$\Rightarrow \hat{\beta} = (\mathbf{X}^T\mathbf{X} + \lambda I)^{-1}\mathbf{X}^T\mathbf{y}$$

with $\lambda \geq 0$ a **complexity parameter** / **regularization parameter**.

As

- solutions of ridge regression are not equivariant under scaling of the predictors, and as

- it does not make sense to include a constraint for the parameter of the intercept

data is normalized before ridge regression:

$$x'_{i,j} := \frac{x_{i,j} - \bar{x}_{.,j}}{\hat{\sigma}(x_{.,j})}$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
61/70

Shrinkage / Ridge Regression (2/3)

Ridge regression is a combination of

$$\underbrace{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}_{} + \lambda \underbrace{\sum_{j=1}^{p}\beta_j^2}_{}$$

$= \text{L2 loss} \quad + \lambda \text{ L2 regularization}$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute BW/WI & Institute for Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2011/12
62/70

Shrinkage / Ridge Regression (3/3) / Tikhonov Regularization (1/2)

L2 regularization / **Tikhonov regularization** can be derived for linear regression as follows:

Treat the true parameters θ_j as random variables Θ_j with the following distribution (**prior**):

$$\Theta_j \sim \mathcal{N}(0, \sigma_\Theta), \quad j = 1, \ldots, p$$

Then the **joint likelihood of the data and the parameters** is

$$L_{\mathcal{D},\Theta}(\theta) := \left(\prod_{i=1}^{n} p(x_i, y_i \mid \theta) \right) \prod_{j=1}^{p} p(\Theta_j = \theta_j)$$

and the conditional joint log likelihood of the data and the parameters accordingly

$$\log L_{\mathcal{D},\Theta}^{\mathsf{cond}}(\theta) := \left(\sum_{i=1}^{n} \log p(y_i \mid x_i, \theta) \right) + \sum_{j=1}^{p} \log p(\Theta_j = \theta_j)$$

and

$$\log p(\Theta_j = \theta_j) = \log \frac{1}{\sqrt{2\pi}\sigma_\Theta} e^{-\frac{\theta_j^2}{2\sigma_\Theta^2}} = -\log(\sqrt{2\pi}\sigma_\Theta) - \frac{\theta_j^2}{2\sigma_\Theta^2}$$

Shrinkage / Ridge Regression (3/3) / Tikhonov Regularization (2/2)

Dropping the terms that do not depend on θ_j yields:

$$\log L_{\mathcal{D},\Theta}^{\text{cond}}(\theta) := \left(\sum_{i=1}^{n} \log p(y_i \mid x_i, \theta) \right) + \sum_{j=1}^{p} \log p(\Theta_j = \theta_j)$$

$$\propto \left(\sum_{i=1}^{n} \log p(y_i \mid x_i, \theta) \right) - \frac{1}{2\sigma_\Theta^2} \sum_{j=1}^{p} \theta_j^2$$

This also gives a semantics to the complexity / regularization parameter λ:

$$\lambda = \frac{1}{2\sigma_\Theta^2}$$

but σ_Θ^2 is unknown. (We will see methods to estimate λ later on.)

The parameters θ that maximize the joint likelihood of the data and the parameters are called **Maximum Aposteriori Estimators (MAP estimators)**.

Putting a prior on the parameters is called **Bayesian approach.**

How to compute ridge regression / Example

Fit $\qquad$ to the data:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon$$

x_1	x_2	y
1	2	3
2	3	2
4	1	7
5	5	1

$$X = \begin{pmatrix} 1 & 1 & 2 \\ 1 & 2 & 3 \\ 1 & 4 & 1 \\ 1 & 5 & 5 \end{pmatrix}, \quad Y = \begin{pmatrix} 3 \\ 2 \\ 7 \\ 1 \end{pmatrix}, \quad I := \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

$$X^T X = \begin{pmatrix} 4 & 12 & 11 \\ 12 & 46 & 37 \\ 11 & 37 & 39 \end{pmatrix}, \quad X^T X + 5I = \begin{pmatrix} \textcolor{red}{9} & 12 & 11 \\ 12 & \textcolor{red}{51} & 37 \\ 11 & 37 & \textcolor{red}{44} \end{pmatrix}, \quad X^T Y = \begin{pmatrix} 13 \\ 40 \\ 24 \end{pmatrix}$$

Cases of Different Importance

Sometimes different cases are of different importance, e.g., if their measurements are of different accurracy or reliability.

Example: assume the left most point is known to be measured with lower reliability.

Thus, the model does not need to fit to this point equally as well as it needs to do to the other points.

I.e., residuals of this point should get lower weight than the others.

66/70

Case Weights

In such situations, each case (x_i, y_i) is assigned a **case weight** $w_i \geq 0$:

- the higher the weight, the more important the case.

- cases with weight 0 should be treated as if they have been discarded from the data set.

Case weights can be managed as an additional pseudo-variable w in applications.

Weighted Least Squares Estimates

Formally, one tries to minimize the **weighted residual sum of squares**

$$\sum_{i=1}^{n} w_i (y_i - \hat{y}_i)^2 = ||\mathbf{W}^{\frac{1}{2}}(\mathbf{y} - \hat{\mathbf{y}})||^2$$

with

$$\mathbf{W} := \begin{pmatrix} w_1 & & & 0 \\ & w_2 & & \\ & & \ddots & \\ 0 & & & w_n \end{pmatrix}$$
The same argument as for the unweighted case results in the **weighted least squares estimates**

$$\mathbf{X}^T \mathbf{W} \mathbf{X} \hat{\beta} = \mathbf{X}^T \mathbf{W} \mathbf{y}$$

Weighted Least Squares Estimates / Example

Do downweight the left most point, we assign case weights as follows:

w	x	y
1	5.65	3.54
1	3.37	1.75
1	1.97	0.04
1	3.70	4.42
0.1	0.15	3.85
1	8.14	8.75
1	7.42	8.11
1	6.59	5.64
1	1.77	0.18
1	7.74	8.30

Summary

- For regression, **linear models** of type $Y = \langle X, \beta \rangle + \epsilon$ can be used to predict a quantitative Y based on several (quantitative) X.

- The **ordinary least squares estimates (OLS)** are the parameters with minimal residual sum of squares (RSS). They coincide with the **maximum likelihood estimates (MLE)**.

- OLS estimates can be computed by solving the **system of linear equations** $\mathbf{X}^T \mathbf{X} \hat{\beta} = \mathbf{X}^T \mathbf{Y}$.

- The **variance of the OLS estimates** can be computed likewise $((\mathbf{X}^T \mathbf{X})^{-1} \hat{\sigma}^2)$.

- For deciding about inclusion of predictors as well as of powers and interactions of predictors in a model, **model selection measures** (AIC, BIC) and different search strategies such as forward and backward search are available.
