5. Model Selection

6. Case Weights

Example

Example: how does gas consumption depend on external temperature?
(Whiteside, 1960s).

weekly measurements of

- average external temperature
- total gas consumption
(in 1000 cubic feet)

A third variable encodes two heating seasons, before and after wall insulation.

How does gas consumption depend on external temperature?

How much gas is needed for a given temperature ?

Example

linear model

Machine Learning / 1. The Regression Problem

Variable Types and Coding

The most common variable types:

numerical / interval-scaled / quantitative

where differences and quotients etc. are meaningful,
usually with domain $\mathcal{X} := \mathbb{R}$,
e.g., temperature, size, weight.

nominal / discrete / categorical / qualitative / factor

where differences and quotients are not defined,
usually with a finite, enumerated domain,
e.g., $\mathcal{X} := \{\text{red, green, blue}\}$
or $\mathcal{X} := \{\text{a, b, c, \dots, y, z}\}$.

ordinal / ordered categorical

where levels are ordered, but differences and quotients are not defined,
usually with a finite, enumerated domain,
e.g., $\mathcal{X} := \{\text{small, medium, large}\}$

Variable Types and Coding

Nominals are usually encoded as binary **dummy variables**:

$$\delta_{x_0}(X) := \begin{cases} 1, & \text{if } X = x_0, \\ 0, & \text{else} \end{cases}$$

one for each $x_0 \in \mathcal{X}$ (but one).

Example: $\mathcal{X} := \{\text{red, green, blue}\}$

Replace

one variable X with 3 levels: red, green, blue

by

two variables $\delta_{\text{red}}(X)$ and $\delta_{\text{green}}(X)$ with 2 levels each: 0, 1

X	$\delta_{\text{red}}(X)$	$\delta_{\text{green}}(X)$
red	1	0
green	0	1
blue	0	0
—	1	1

The Regression Problem Formally

Let

X_1, X_2, \dots, X_p be random variables called **predictors** (or **inputs**, **covariates**, **features**).

Let $\mathcal{X}_1, \mathcal{X}_2, \dots, \mathcal{X}_p$ be their domains.

We write shortly

$$X := (X_1, X_2, \dots, X_p)$$

for the vector of random predictor variables and

$$\mathcal{X} := \mathcal{X}_1 \times \mathcal{X}_2 \times \dots \times \mathcal{X}_p$$

for its domain.

Y be a random variable called **target** (or **output**, **response**).

Let \mathcal{Y} be its domain.

$\mathcal{D} \subseteq \mathcal{X} \times \mathcal{Y}$ be a (multi)set of instances of the unknown joint distribution $p(X, Y)$ of predictors and target called **data**.

\mathcal{D} is often written as enumeration

$$\mathcal{D} = \{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}$$

The Regression Problem Formally (v0)

The task of regression and classification is to predict Y based on X , i.e., to estimate

$$\hat{y}(x) := r(x) := E(Y | X = x) = \int y p(y|x) dy$$

based on data (called **regression function**).

If Y is numerical, the task is called **regression**.

If Y is nominal, the task is called **classification**.

The Regression Problem Formally (v1)

Let \mathcal{X} be any set (called **predictor space**).

Given

– a set $\mathcal{D}^{\text{train}} \subseteq \mathcal{X} \times \mathbb{R}$ of data (called **training set**),

compute a **regression function**

$$\hat{y} : \mathcal{X} \rightarrow \mathbb{R}$$

s.t. for a set $\mathcal{D}^{\text{test}} \subseteq \mathcal{X} \times \mathbb{R}$ of data (called **test set**) not available during training, the test error

$$\text{err}(\hat{y}; \mathcal{D}^{\text{test}}) := \frac{1}{|\mathcal{D}^{\text{test}}|} \sum_{(x,y) \in \mathcal{D}^{\text{test}}} (y - \hat{y}(x))^2$$

is minimal.

The Regression Problem Formally (v2)

Let \mathcal{X} be any set (called **predictor space**).

Given

- a set $\mathcal{D}^{\text{train}} \subseteq \mathcal{X} \times \mathbb{R}$ of data (called **training set**),
- a loss function $\ell : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ that measures how bad it is to predict value \hat{y} if the true value is y ,

compute a **regression function**

$$\hat{y} : \mathcal{X} \rightarrow \mathbb{R}$$

s.t. for a set $\mathcal{D}^{\text{test}} \subseteq \mathcal{X} \times \mathbb{R}$ of data (called **test set**) not available during training, the test error

$$\text{err}(\hat{y}; \mathcal{D}^{\text{test}}) := \frac{1}{|\mathcal{D}^{\text{test}}|} \sum_{(x,y) \in \mathcal{D}^{\text{test}}} \ell(y, \hat{y}(x))$$

is minimal.

Examples:

$$\ell(y, \hat{y}) := (y - \hat{y})^2$$

The Regression Problem Formally (v3)

Let \mathcal{X} be any set (called **predictor space**), and
 \mathcal{Y} be any set (called **target space**).

Given

- a set $\mathcal{D}^{\text{train}} \subseteq \mathcal{X} \times \mathcal{Y}$ of data (called **training set**),
- a loss function $\ell : \mathcal{Y} \times \mathcal{Y} \rightarrow \mathbb{R}$ that measures how bad it is to predict value \hat{y} if the true value is y ,

compute a **prediction function**

$$\hat{y} : \mathcal{X} \rightarrow \mathcal{Y}$$

s.t. for a set $\mathcal{D}^{\text{test}} \subseteq \mathcal{X} \times \mathbb{R}$ of data (called **test set**) not available during training, the test error

$$\text{err}(\hat{y}; \mathcal{D}^{\text{test}}) := \frac{1}{|\mathcal{D}^{\text{test}}|} \sum_{(x,y) \in \mathcal{D}^{\text{test}}} \ell(y, \hat{y}(x))$$

is minimal.

Examples:

$$\mathcal{Y} := \mathbb{R}, \quad \ell(y, \hat{y}) := (y - \hat{y})^2$$

The Regression Problem Formally (v4)

Let \mathcal{X} be any set (called **predictor space**),
 \mathcal{Y} be any set (called **target space**), e.g., and
 $p : \mathcal{X} \times \mathcal{Y} \rightarrow \mathbb{R}_0^+$ be a joint distribution / density.

Given

- a sample $\mathcal{D}^{\text{train}} \subseteq \mathcal{X} \times \mathcal{Y}$ (called **training set**), drawn from p ,
- a loss function $\ell : \mathcal{Y} \times \mathcal{Y} \rightarrow \mathbb{R}$ that measures how bad it is to predict value \hat{y} if the true value is y ,

compute a **prediction function**

$$\hat{y} : \mathcal{X} \rightarrow \mathcal{Y}$$

s.t. for another sample $\mathcal{D}^{\text{test}} \subseteq \mathcal{X} \times \mathbb{R}$ (called **test set**) drawn from the same distribution p , not available during training, the test error

$$\text{err}(\hat{y}; \mathcal{D}^{\text{test}}) := \frac{1}{|\mathcal{D}^{\text{test}}|} \sum_{(x,y) \in \mathcal{D}^{\text{test}}} \ell(y, \hat{y}(x))$$

is minimal.

The Regression Problem Formally (v5)

Let \mathcal{X} be any set (called **predictor space**),
 \mathcal{Y} be any set (called **target space**), and
 $p : \mathcal{X} \times \mathcal{Y} \rightarrow \mathbb{R}_0^+$ be a joint distribution / density.

Given

- a sample $\mathcal{D}^{\text{train}} \subseteq \mathcal{X} \times \mathcal{Y}$ (called **training set**), drawn from p ,
- a loss function $\ell : \mathcal{Y} \times \mathcal{Y} \rightarrow \mathbb{R}$ that measures how bad it is to predict value \hat{y} if the true value is y ,

compute a **prediction function**

$$\hat{y} : \mathcal{X} \rightarrow \mathcal{Y}$$

with minimal risk

$$\text{risk}(\hat{y}; p) := \int_{\mathcal{X} \times \mathcal{Y}} \ell(y, \hat{y}) p(x, y) d(x, y)$$

Explanation: $\text{risk}(\hat{y}; p)$ can be estimated by the **empirical risk**

$$\text{risk}(\hat{y}; \mathcal{D}^{\text{test}}) := \frac{1}{|\mathcal{D}^{\text{test}}|} \sum_{(x,y) \in \mathcal{D}^{\text{test}}} \ell(y, \hat{y}(x))$$

Simple Linear Regression Model

Make it simple:

- the predictor X is simple, i.e., one-dimensional ($X = X_1$).
- $r(x)$ is assumed to be linear:

$$r(x) = \beta_0 + \beta_1 x$$

- assume that the variance does not depend on X :

$$Y = \beta_0 + \beta_1 X + \epsilon, \quad E(\epsilon|X) = 0, V(\epsilon|X) = \sigma^2$$

- 3 parameters:

β_0 **intercept** (sometimes also called bias)

β_1 **slope**

σ^2 **variance**

Simple Linear Regression Model

parameter estimates

$$\hat{\beta}_0, \hat{\beta}_1, \hat{\sigma}^2$$

fitted line

$$\hat{r}(x) := \hat{\beta}_0 + \hat{\beta}_1 x$$

predicted / fitted values

$$\hat{y}_i := \hat{r}(x_i)$$

residuals

$$\hat{\epsilon}_i := y_i - \hat{y}_i = y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i)$$

residual sums of squares (RSS) / square loss / L2 loss

$$\text{RSS} = \sum_{i=1}^n \hat{\epsilon}_i^2$$

Machine Learning / 2. Simple Linear Regression

How to estimate the parameters?

Example:

Given the data $\mathcal{D} := \{(1, 2), (2, 3), (4, 6)\}$, predict a value for $x = 3$.

How to estimate the parameters?

Example:

Given the data $\mathcal{D} := \{(1, 2), (2, 3), (4, 6)\}$, predict a value for $x = 3$.

Line through first two points:

$$\hat{\beta}_1 = \frac{y_2 - y_1}{x_2 - x_1} = 1$$

$$\hat{\beta}_0 = y_1 - \hat{\beta}_1 x_1 = 1$$

RSS:

i	y_i	\hat{y}_i	$(y_i - \hat{y}_i)^2$
1	2	2	0
2	3	3	0
3	6	5	1
Σ			1

$$\hat{r}(3) = 4$$

How to estimate the parameters?

Example:

Given the data $\mathcal{D} := \{(1, 2), (2, 3), (4, 6)\}$, predict a value for $x = 3$.

Line through first and last point:

$$\hat{\beta}_1 = \frac{y_3 - y_1}{x_3 - x_1} = 4/3 = 1.333$$

$$\hat{\beta}_0 = y_1 - \hat{\beta}_1 x_1 = 2/3 = 0.667$$

RSS:

i	y_i	\hat{y}_i	$(y_i - \hat{y}_i)^2$
1	2	2	0
2	3	3.333	0.111
3	6	6	0
Σ			0.111

$$\hat{r}(3) = 4.667$$

Least Squares Estimates / Definition

In principle, there are many different methods to estimate the parameters $\hat{\beta}_0$, $\hat{\beta}_1$ and $\hat{\sigma}^2$ from data — depending on the properties the solution should have.

The **least squares estimates** are those parameters that minimize

$$\text{RSS} = \sum_{i=1}^n \hat{\epsilon}_i^2 = \sum_{i=1}^n (y_i - \hat{y}_i)^2 = \sum_{i=1}^n (y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i))^2$$

They can be written in closed form as follows:

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2}$$

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$

$$\hat{\sigma}^2 = \frac{1}{n-2} \sum_{i=1}^n \hat{\epsilon}_i^2$$

Least Squares Estimates / Proof

Proof (1/2):

$$\text{RSS} = \sum_{i=1}^n (y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i))^2$$

$$\frac{\partial \text{RSS}}{\partial \hat{\beta}_0} = \sum_{i=1}^n 2(y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i))(-1) \stackrel{!}{=} 0$$

$$\implies n\hat{\beta}_0 = \sum_{i=1}^n (y_i - \hat{\beta}_1 x_i)$$

Least Squares Estimates / Proof

Proof (2/2):

$$\begin{aligned}
 \text{RSS} &= \sum_{i=1}^n (y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i))^2 \\
 &= \sum_{i=1}^n (y_i - (\bar{y} - \hat{\beta}_1 \bar{x}) - \hat{\beta}_1 x_i)^2 \\
 &= \sum_{i=1}^n (y_i - \bar{y} - \hat{\beta}_1 (x_i - \bar{x}))^2 \\
 \frac{\partial \text{RSS}}{\partial \hat{\beta}_1} &= \sum_{i=1}^n 2(y_i - \bar{y} - \hat{\beta}_1 (x_i - \bar{x}))(-1)(x_i - \bar{x}) \stackrel{!}{=} 0 \\
 \Rightarrow \hat{\beta}_1 &= \frac{\sum_{i=1}^n (y_i - \bar{y})(x_i - \bar{x})}{\sum_{i=1}^n (x_i - \bar{x})^2}
 \end{aligned}$$

Machine Learning / 2. Simple Linear Regression

Least Squares Estimates / Example

Example:

Given the data $\mathcal{D} := \{(1, 2), (2, 3), (4, 6)\}$, predict a value for $x = 3$.

Assume simple linear model.

$$\bar{x} = 7/3, \bar{y} = 11/3.$$

i	$x_i - \bar{x}$	$y_i - \bar{y}$	$(x_i - \bar{x})^2$	$(x_i - \bar{x})(y_i - \bar{y})$
1	$-4/3$	$-5/3$	$16/9$	$20/9$
2	$-1/3$	$-2/3$	$1/9$	$2/9$
3	$5/3$	$7/3$	$25/9$	$35/9$
Σ			$42/9$	$57/9$

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{57}{42} = 1.357$$

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x} = \frac{11}{3} - \frac{57}{42} \cdot \frac{7}{3} = \frac{63}{126} = 0.5$$

Least Squares Estimates / Example

Example:

Given the data $\mathcal{D} := \{(1, 2), (2, 3), (4, 6)\}$, predict a value for $x = 3$.

Assume simple linear model.

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2} = 57/42 = 1.357$$

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x} = \frac{11}{3} - \frac{57}{42} \cdot \frac{7}{3} = \frac{63}{126} = 0.5$$

RSS:

i	y_i	\hat{y}_i	$(y_i - \hat{y}_i)^2$
1	2	1.857	0.020
2	3	3.214	0.046
3	6	5.929	0.005
Σ			0.071

$$\hat{r}(3) = 4.571$$

A Generative Model

So far we assumed the model

$$Y = \beta_0 + \beta_1 X + \epsilon, \quad E(\epsilon|X) = 0, V(\epsilon|X) = \sigma^2$$

where we required some properties of the errors, but not its exact distribution.

If we make assumptions about its distribution, e.g.,

$$\epsilon|X \sim \mathcal{N}(0, \sigma^2)$$

and thus

$$Y|X = x \sim \mathcal{N}(\beta_0 + \beta_1 x, \sigma^2)$$

we can sample from this model.

Maximum Likelihood Estimates (MLE)

Let $p(X, Y | \theta)$ be a joint probability density function for X and Y with parameters θ .

Likelihood:

$$L_{\mathcal{D}}(\theta) := \prod_{i=1}^n p(x_i, y_i | \theta)$$

The likelihood describes the probability of the data.

The **maximum likelihood estimates (MLE)** are those parameters that maximize the likelihood.

Least Squares Estimates and Maximum Likelihood Estimates

Likelihood:

$$L_{\mathcal{D}}(\hat{\beta}_0, \hat{\beta}_1, \hat{\sigma}^2) := \prod_{i=1}^n \hat{p}(x_i, y_i) = \prod_{i=1}^n \hat{p}(y_i | x_i) p(x_i) = \prod_{i=1}^n \hat{p}(y_i | x_i) \prod_{i=1}^n p(x_i)$$

Conditional likelihood:

$$L_{\mathcal{D}}^{\text{cond}}(\hat{\beta}_0, \hat{\beta}_1, \hat{\sigma}^2) := \prod_{i=1}^n \hat{p}(y_i | x_i) = \prod_{i=1}^n \frac{1}{\sqrt{2\pi}\hat{\sigma}} e^{-\frac{(y_i - \hat{y}_i)^2}{2\hat{\sigma}^2}} = \frac{1}{\sqrt{2\pi}^n \hat{\sigma}^n} e^{-\frac{1}{2\hat{\sigma}^2} \sum_{i=1}^n (y_i - \hat{y}_i)^2}$$

Conditional log-likelihood:

$$\log L_{\mathcal{D}}^{\text{cond}}(\hat{\beta}_0, \hat{\beta}_1, \hat{\sigma}^2) \propto -n \log \hat{\sigma} - \frac{1}{2\hat{\sigma}^2} \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

\implies if we assume normality, the maximum likelihood estimates are just the least squares estimates.

Implementation Details

```

1. The Regression Problem

2. Simple Linear Regression

3. Multiple Regression

4. Variable Interactions

5. Model Selection

6. Case Weights

Several predictors

Several predictor variables X_1, X_2, \dots, X_p :

$$\begin{aligned} Y &= \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p + \epsilon \\ &= \beta_0 + \sum_{i=1}^p \beta_i X_i + \epsilon \end{aligned}$$

with $p + 1$ parameters $\beta_0, \beta_1, \dots, \beta_p$.

Linear form

Several predictor variables X_1, X_2, \dots, X_p :

$$\begin{aligned} Y &= \beta_0 + \sum_{i=1}^p \beta_i X_i + \epsilon \\ &= \langle \beta, X \rangle + \epsilon \end{aligned}$$

where

$$\beta := \begin{pmatrix} \beta_0 \\ \beta_1 \\ \vdots \\ \beta_p \end{pmatrix}, \quad X := \begin{pmatrix} 1 \\ X_1 \\ \vdots \\ X_p \end{pmatrix},$$

Thus, the intercept is handled like any other parameter, for the artificial constant variable $X_0 \equiv 1$.

Simultaneous equations for the whole dataset

For the whole dataset $(x_1, y_1), \dots, (x_n, y_n)$:

$$\mathbf{Y} = \mathbf{X}\beta + \epsilon$$

where

$$\mathbf{Y} := \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix}, \quad \mathbf{X} := \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} x_{1,1} & x_{1,2} & \dots & x_{1,p} \\ \vdots & \vdots & \vdots & \vdots \\ x_{n,1} & x_{n,2} & \dots & x_{n,p} \end{pmatrix}, \quad \epsilon := \begin{pmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{pmatrix},$$

Least squares estimates

Least squares estimates $\hat{\beta}$ minimize

$$\|\mathbf{Y} - \hat{\mathbf{Y}}\|^2 = \|\mathbf{Y} - \mathbf{X}\hat{\beta}\|^2$$

The least squares estimates $\hat{\beta}$ are computed via

$$\mathbf{X}^T \mathbf{X} \hat{\beta} = \mathbf{X}^T \mathbf{Y}$$

Proof:

$$\|\mathbf{Y} - \mathbf{X}\hat{\beta}\|^2 = \langle \mathbf{Y} - \mathbf{X}\hat{\beta}, \mathbf{Y} - \mathbf{X}\hat{\beta} \rangle$$

$$\frac{\partial(\dots)}{\partial \hat{\beta}} = 2\langle -\mathbf{X}, \mathbf{Y} - \mathbf{X}\hat{\beta} \rangle = -2(\mathbf{X}^T \mathbf{Y} - \mathbf{X}^T \mathbf{X} \hat{\beta}) \stackrel{!}{=} 0$$

How to compute least squares estimates $\hat{\beta}$

Solve the $p \times p$ system of linear equations

$$\mathbf{X}^T \mathbf{X} \hat{\beta} = \mathbf{X}^T \mathbf{Y}$$

i.e., $Ax = b$ (with $A := \mathbf{X}^T \mathbf{X}$, $b = \mathbf{X}^T \mathbf{Y}$, $x = \hat{\beta}$).

There are several numerical methods available:

1. Gaussian elimination
2. Cholesky decomposition
3. QR decomposition

How to compute least squares estimates $\hat{\beta}$ / Example

Given is the following data:

x_1	x_2	y
1	2	3
2	3	2
4	1	7
5	5	1

Predict a y value for $x_1 = 3, x_2 = 4$.

Machine Learning / 3. Multiple Regression

How to compute least squares estimates $\hat{\beta}$ / Example

$$Y = \beta_0 + \beta_1 X_1 + \epsilon$$

$$= 2.95 + 0.1 X_1 + \epsilon$$

$$Y = \beta_0 + \beta_2 X_2 + \epsilon$$

$$= 6.943 - 1.343 X_2 + \epsilon$$

$$\hat{y}(x_1 = 3) = 3.25$$

$$\hat{y}(x_2 = 4) = 1.571$$

How to compute least squares estimates $\hat{\beta}$ / Example

Now fit

to the data:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon$$

x_1	x_2	y
1	2	3
2	3	2
4	1	7
5	5	1

$$\mathbf{X} = \begin{pmatrix} 1 & 1 & 2 \\ 1 & 2 & 3 \\ 1 & 4 & 1 \\ 1 & 5 & 5 \end{pmatrix}, \quad \mathbf{Y} = \begin{pmatrix} 3 \\ 2 \\ 7 \\ 1 \end{pmatrix}$$

$$\mathbf{X}^T \mathbf{X} = \begin{pmatrix} 4 & 12 & 11 \\ 12 & 46 & 37 \\ 11 & 37 & 39 \end{pmatrix}, \quad \mathbf{X}^T \mathbf{Y} = \begin{pmatrix} 13 \\ 40 \\ 24 \end{pmatrix}$$

Machine Learning / 3. Multiple Regression

How to compute least squares estimates $\hat{\beta}$ / Example

$$\left(\begin{array}{ccc|c} 4 & 12 & 11 & 13 \\ 12 & 46 & 37 & 40 \\ 11 & 37 & 39 & 24 \end{array} \right) \sim \left(\begin{array}{ccc|c} 4 & 12 & 11 & 13 \\ 0 & 10 & 4 & 1 \\ 0 & 16 & 35 & -47 \end{array} \right) \sim \left(\begin{array}{ccc|c} 4 & 12 & 11 & 13 \\ 0 & 10 & 4 & 1 \\ 0 & 0 & 143 & -243 \end{array} \right)$$

$$\sim \left(\begin{array}{ccc|c} 4 & 12 & 11 & 13 \\ 0 & 1430 & 0 & 1115 \\ 0 & 0 & 143 & -243 \end{array} \right) \sim \left(\begin{array}{ccc|c} 286 & 0 & 0 & 1597 \\ 0 & 1430 & 0 & 1115 \\ 0 & 0 & 143 & -243 \end{array} \right)$$

i.e.,

$$\hat{\beta} = \begin{pmatrix} 1597/286 \\ 1115/1430 \\ -243/143 \end{pmatrix} \approx \begin{pmatrix} 5.583 \\ 0.779 \\ -1.699 \end{pmatrix}$$

How to compute least squares estimates $\hat{\beta}$ / Example

Course on Machine Learning, winter term 2013/14

42/75

Machine Learning / 3. Multiple Regression

How to compute least squares estimates $\hat{\beta}$ / Example

To visually assess the model fit, a plot

residuals $\hat{\epsilon} = y - \hat{y}$ vs. true values y

can be plotted:

The Normal Distribution (also Gaussian)

written as:

$$X \sim \mathcal{N}(\mu, \sigma^2)$$

with parameters:

 μ mean, σ standard deviance.**probability density function (pdf):**

$$\phi(x) := \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

**cumulative distribution function (cdf):**

$$\Phi(x) := \int_{-\infty}^x \phi(t) dt$$

 Φ^{-1} is called **quantile function**. Φ and Φ^{-1} have no analytical form, but have to be computed numerically.Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute of Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2013/14

44/75

The t Distribution

written as:

$$X \sim t_p$$

with parameter:

 p degrees of freedom.**probability density function (pdf):**

$$p(x) := \frac{\Gamma(\frac{p+1}{2})}{\sqrt{p\pi} \Gamma(\frac{p}{2})} \left(1 + \frac{x^2}{p}\right)^{-\frac{p+1}{2}}$$

$$t_p \xrightarrow{p \rightarrow \infty} \mathcal{N}(0, 1)$$

The χ^2 Distribution

written as:

$$X \sim \chi_p^2$$

with parameter:

 p degrees of freedom.**probability density function (pdf):**

$$p(x) := \frac{1}{\Gamma(p/2)2^{p/2}} x^{p/2-1} e^{-x/2}, \quad x \geq 0$$

If $X_1, \dots, X_p \sim \mathcal{N}(0, 1)$, then

$$Y := \sum_{i=1}^p X_i^2 \sim \chi_p^2$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute of Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2013/1420
46/75

Parameter Variance

 $\hat{\beta} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{Y}$ is an unbiased estimator for β (i.e., $E(\hat{\beta}) = \beta$).

Its variance is

$$V(\hat{\beta}) = (\mathbf{X}^T \mathbf{X})^{-1} \sigma^2$$

proof:

$$\hat{\beta} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{Y} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T (\mathbf{X} \beta + \epsilon) = \beta + (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \epsilon$$

As $E(\epsilon) = 0$: $E(\hat{\beta}) = \beta$

$$\begin{aligned} V(\hat{\beta}) &= E((\hat{\beta} - E(\hat{\beta}))(\hat{\beta} - E(\hat{\beta}))^T) \\ &= E((\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \epsilon \epsilon^T \mathbf{X} (\mathbf{X}^T \mathbf{X})^{-1}) \\ &= (\mathbf{X}^T \mathbf{X})^{-1} \sigma^2 \end{aligned}$$

Parameter Variance

An unbiased estimator for σ^2 is

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_{i=1}^n \hat{\epsilon}_i^2 = \frac{1}{n-p} \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

If $\epsilon \sim \mathcal{N}(0, \sigma^2)$, then

$$\hat{\beta} \sim \mathcal{N}(\beta, (\mathbf{X}^T \mathbf{X})^{-1} \sigma^2)$$

Furthermore

$$(n-p)\hat{\sigma}^2 \sim \sigma^2 \chi_{n-p}^2$$

Parameter Variance / Standardized coefficient

standardized coefficient (“z-score”):

$$z_i := \frac{\hat{\beta}_i}{\widehat{\text{se}}(\hat{\beta}_i)}, \quad \text{with } \widehat{\text{se}}^2(\hat{\beta}_i) \text{ the } i\text{-th diagonal element of } (\mathbf{X}^T \mathbf{X})^{-1} \hat{\sigma}^2$$

z_i would be $z_i \sim \mathcal{N}(0, 1)$ if σ is known (under $H_0 : \beta_i = 0$).

With estimated $\hat{\sigma}$ it is $z_i \sim t_{n-p}$.

The Wald test for $H_0 : \beta_i = 0$ with size α is:

$$\text{reject } H_0 \text{ if } |z_i| = \left| \frac{\hat{\beta}_i}{\widehat{\text{se}}(\hat{\beta}_i)} \right| > F_{t_{n-p}}^{-1} \left(1 - \frac{\alpha}{2} \right)$$

i.e., its p -value is

$$p\text{-value}(H_0 : \beta_i = 0) = 2(1 - F_{t_{n-p}}(|z_i|)) = 2(1 - F_{t_{n-p}}\left(\left| \frac{\hat{\beta}_i}{\widehat{\text{se}}(\hat{\beta}_i)} \right| \right))$$

and small p -values such as 0.01 and 0.05 are good.

Parameter Variance / Confidence interval

The $1 - \alpha$ confidence interval for β_i :

$$\beta_i \pm F_{t_{n-p}}^{-1}\left(1 - \frac{\alpha}{2}\right) \widehat{\text{se}}(\hat{\beta}_i)$$

For large n , $F_{t_{n-p}}$ converges to the standard normal cdf Φ .

As $\Phi^{-1}\left(1 - \frac{0.05}{2}\right) \approx 1.95996 \approx 2$, the rule-of-thumb for a 5% confidence interval is

$$\beta_i \pm 2\widehat{\text{se}}(\hat{\beta}_i)$$

Parameter Variance / Example

We have already fitted

$$\begin{aligned} \hat{Y} &= \hat{\beta}_0 + \hat{\beta}_1 X_1 + \hat{\beta}_2 X_2 \\ &= 5.583 + 0.779 X_1 - 1.699 X_2 \end{aligned}$$

to the data:

x_1	x_2	y	\hat{y}	$\hat{\epsilon}^2 = (y - \hat{y})^2$
1	2	3	2.965	0.00122
2	3	2	2.045	0.00207
4	1	7	7.003	0.0000122
5	5	1	0.986	0.000196
RSS				0.00350

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_{i=1}^n \hat{\epsilon}_i^2 = \frac{1}{4-3} 0.00350 = 0.00350$$

$$(X^T X)^{-1} \hat{\sigma}^2 = \begin{pmatrix} 0.00520 & -0.00075 & -0.00076 \\ -0.00075 & 0.00043 & -0.00020 \\ -0.00076 & -0.00020 & 0.00049 \end{pmatrix}$$

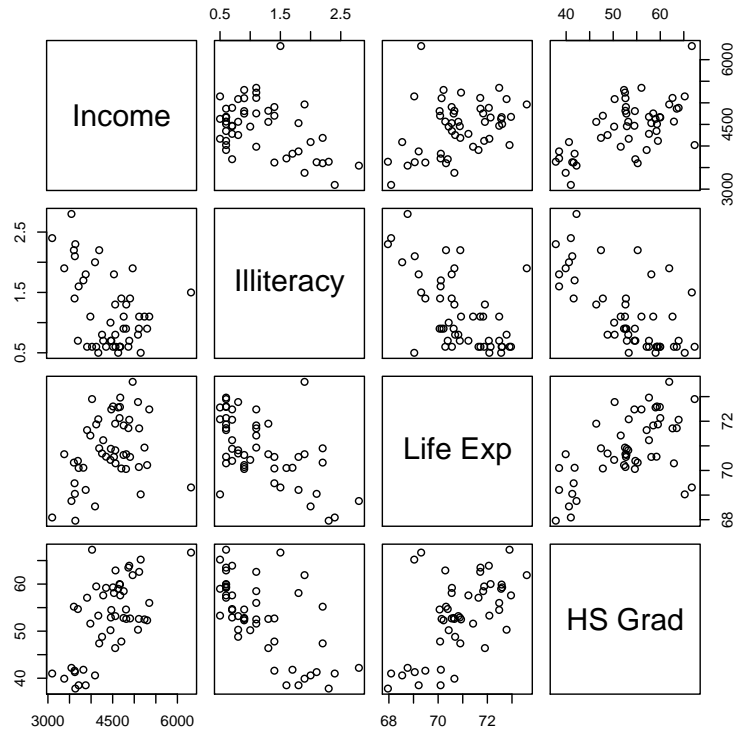

covariate	$\hat{\beta}_i$	$\widehat{\text{se}}(\hat{\beta}_i)$	z-score	p-value
(intercept)	5.583	0.0721	77.5	0.0082
X_1	0.779	0.0207	37.7	0.0169
X_2	-1.699	0.0221	-76.8	0.0083

Parameter Variance / Example 2

Example: sociographic data of the 50 US states in 1977.

state dataset:

- income (per capita, 1974),
- illiteracy (percent of population, 1970),
- life expectancy (in years, 1969–71),
- percent high-school graduates (1970).
- population (July 1, 1975)
- murder rate per 100,000 population (1976)
- mean number of days with minimum temperature below freezing (1931–1960) in capital or large city
- land area in square miles

Machine Learning / 4. Variable Interactions

Need for higher orders

Assume a target variable does not depend linearly on a predictor variable, but say quadratic.

Example: way length vs. duration of a moving object with constant acceleration a .

$$s(t) = \frac{1}{2}at^2 + \epsilon$$

Can we catch such a dependency?

Can we catch it with a linear model?

Need for general transformations

To describe many phenomena, even more complex functions of the input variables are needed.

Example: the number of cells n vs. duration of growth t :

$$n = \beta e^{\alpha t} + \epsilon$$

n does not depend on t directly, but on $e^{\alpha t}$ (with a known α).

Need for variable interactions

In a linear model with two predictors

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon$$

Y depends on both, X_1 and X_2 .

But changes in X_1 will affect Y the same way, regardless of X_2 .

There are problems where X_2 mediates or influences the way X_1 affects Y , e.g. : the way length s of a moving object vs. its constant velocity v and duration t :

$$s = vt + \epsilon$$

Then an additional $1s$ duration will increase the way length not in a uniform way (regardless of the velocity), but a little for small velocities and a lot for large velocities.

v and t are said to interact: y does not depend only on each predictor separately, but also on their product.

Derived variables

All these cases can be handled by looking at **derived variables**, i.e., instead of

$$Y = \beta_0 + \beta_1 X_1^2 + \epsilon$$

$$Y = \beta_0 + \beta_1 e^{\alpha X_1} + \epsilon$$

$$Y = \beta_0 + \beta_1 X_1 \cdot X_2 + \epsilon$$

one looks at

$$Y = \beta_0 + \beta_1 X'_1 + \epsilon$$

with

$$X'_1 := X_1^2$$

$$X'_1 := e^{\alpha X_1}$$

$$X'_1 := X_1 \cdot X_2$$

Derived variables are computed before the fitting process and taken into account either additional to the original variables or instead of.

1. The Regression Problem

2. Simple Linear Regression

3. Multiple Regression

4. Variable Interactions

5. Model Selection

6. Case Weights

Underfitting

If a model does not well explain the data, e.g., if the true model is quadratic, but we try to fit a linear model, one says, the model **underfits**.

Overfitting / Fitting Polynomials of High Degree

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), Institute of Computer Science, University of Hildesheim
Course on Machine Learning, winter term 2013/14

59/75

Overfitting / Fitting Polynomials of High Degree

If to data

$$(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$$

consisting of n points we fit

$$X = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_{n-1} X_{n-1}$$

i.e., a polynomial with degree $n - 1$, then this results in an interpolation of the data points

(if there are no repeated measurements, i.e., points with the same X_1 .)

As the polynomial

$$r(X) = \sum_{i=1}^n y_i \prod_{j \neq i} \frac{X - x_j}{x_i - x_j}$$

is of this type, and has minimal $\text{RSS} = 0$.

Model Selection Measures

Model selection means: we have a set of models, e.g.,

$$Y = \sum_{i=0}^{p-1} \beta_i X_i$$

indexed by p (i.e., one model for each value of p),
make a choice which model **describes** the data best.

If we just look at **losses / fit measures** such as RSS, then

the larger p , the better the fit

or equivalently

the larger p , the lower the loss

as the model with p parameters can be **reparametrized** in a
model with $p' > p$ parameters by setting

$$\beta'_i = \begin{cases} \beta_i, & \text{for } i \leq p \\ 0, & \text{for } i > p \end{cases}$$

Model Selection Measures

One uses **model selection measures** of type

model selection measure = fit – complexity

or equivalently

model selection measure = loss + complexity

The smaller the loss (= lack of fit), the better the model.

The smaller the complexity, the simpler and thus better the
model.

The model selection measure tries to find a trade-off between
fit/loss and complexity.

Model Selection Measures

Akaike Information Criterion (AIC): (maximize)

$$\text{AIC} := \log L - p$$

or (minimize)

$$\text{AIC} := -2 \log L + 2p = -2n \log(\text{RSS}/n) + 2p$$

Bayes Information Criterion (BIC) /

Bayes-Schwarz Information Criterion: (maximize)

$$\text{BIC} := \log L - \frac{p}{2} \log n$$

Variable Backward Selection

summary(mod.full);  
  
mod.opt = stepAIC(mod.full);  
summary(mod.opt);
```

Shrinkage

Model selection operates by

- fitting models for a set of models with varying complexity and then picking the “best one” ex post,
- omitting some parameters completely (i.e., forcing them to be 0)

shrinkage operates by

- including a penalty term directly in the model equation and
- favoring small parameter values in general.

Shrinkage / Ridge Regression [?]

Ridge regression: minimize

$$\begin{aligned} \text{RSS}_\lambda(\hat{\beta}) &= \text{RSS}(\hat{\beta}) + \lambda \sum_{j=1}^p \hat{\beta}_j^2 \\ &= \langle \mathbf{y} - \mathbf{X}\hat{\beta}, \mathbf{y} - \mathbf{X}\hat{\beta} \rangle + \lambda \sum_{j=1}^p \hat{\beta}_j^2 \\ &\Rightarrow \hat{\beta} = (\mathbf{X}^T \mathbf{X} + \lambda I)^{-1} \mathbf{X}^T \mathbf{y} \end{aligned}$$

with $\lambda \geq 0$ a **complexity parameter / regularization parameter**.

As

- solutions of ridge regression are not equivariant under scaling of the predictors, and as
- it does not make sense to include a constraint for the parameter of the intercept

data is normalized before ridge regression:

$$x'_{i,j} := \frac{x_{i,j} - \bar{x}_{.,j}}{\hat{\sigma}(x_{.,j})}$$

Shrinkage / Ridge Regression (2/3)

Ridge regression is a combination of

$$\begin{aligned} &\underbrace{\sum_{i=1}^n (y_i - \hat{y}_i)^2}_{\text{L2 loss}} + \lambda \underbrace{\sum_{j=1}^p \beta_j^2}_{+\lambda \text{ L2 regularization}} \\ &= \text{L2 loss} \quad + \lambda \text{ L2 regularization} \end{aligned}$$

Shrinkage / Ridge Regression (3/3) / Tikhonov Regularization (1/2)

L2 regularization / Tikhonov regularization can be derived for linear regression as follows:

Treat the true parameters θ_j as random variables Θ_j with the following distribution (**prior**):

$$\Theta_j \sim \mathcal{N}(0, \sigma_\Theta), \quad j = 1, \dots, p$$

Then the **joint likelihood of the data and the parameters** is

$$L_{\mathcal{D}, \Theta}(\theta) := \left(\prod_{i=1}^n p(x_i, y_i | \theta) \right) \prod_{j=1}^p p(\Theta_j = \theta_j)$$

and the conditional joint log likelihood of the data and the parameters accordingly

$$\log L_{\mathcal{D}, \Theta}^{\text{cond}}(\theta) := \left(\sum_{i=1}^n \log p(y_i | x_i, \theta) \right) + \sum_{j=1}^p \log p(\Theta_j = \theta_j)$$

and

$$\log p(\Theta_j = \theta_j) = \log \frac{1}{\sqrt{2\pi\sigma_\Theta}} e^{-\frac{\theta_j^2}{2\sigma_\Theta^2}} = -\log(\sqrt{2\pi\sigma_\Theta}) - \frac{\theta_j^2}{2\sigma_\Theta^2}$$

Shrinkage / Ridge Regression (3/3) / Tikhonov Regularization (2/2)

Dropping the terms that do not depend on θ_j yields:

$$\begin{aligned} \log L_{\mathcal{D}, \Theta}^{\text{cond}}(\theta) &:= \left(\sum_{i=1}^n \log p(y_i | x_i, \theta) \right) + \sum_{j=1}^p \log p(\Theta_j = \theta_j) \\ &\propto \left(\sum_{i=1}^n \log p(y_i | x_i, \theta) \right) - \frac{1}{2\sigma_\Theta^2} \sum_{j=1}^p \theta_j^2 \end{aligned}$$

This also gives a semantics to the complexity / regularization parameter λ :

$$\lambda = \frac{1}{2\sigma_\Theta^2}$$

but σ_Θ^2 is unknown. (We will see methods to estimate λ later on.)

The parameters θ that maximize the joint likelihood of the data and the parameters are called **Maximum A posteriori Estimators (MAP estimators)**.

Putting a prior on the parameters is called **Bayesian approach**.

How to compute ridge regression / Example

Fit $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon$ to the data:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon$$

x_1	x_2	y
1	2	3
2	3	2
4	1	7
5	5	1

$$X = \begin{pmatrix} 1 & 1 & 2 \\ 1 & 2 & 3 \\ 1 & 4 & 1 \\ 1 & 5 & 5 \end{pmatrix}, \quad Y = \begin{pmatrix} 3 \\ 2 \\ 7 \\ 1 \end{pmatrix}, \quad I := \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

$$X^T X = \begin{pmatrix} 4 & 12 & 11 \\ 12 & 46 & 37 \\ 11 & 37 & 39 \end{pmatrix}, \quad X^T X + 5I = \begin{pmatrix} 9 & 12 & 11 \\ 12 & 51 & 37 \\ 11 & 37 & 44 \end{pmatrix}, \quad X^T Y = \begin{pmatrix} 13 \\ 40 \\ 24 \end{pmatrix}$$

Course on Machine Learning, winter term 2013/14

70/75

Machine Learning

**1. The Regression Problem****2. Simple Linear Regression****3. Multiple Regression****4. Variable Interactions****5. Model Selection****6. Case Weights**

Cases of Different Importance

Sometimes different cases are of different importance, e.g., if their measurements are of different accuracy or reliability.

Example: assume the left most point is known to be measured with lower reliability.

Thus, the model does not need to fit to this point equally as well as it needs to do to the other points.

I.e., residuals of this point should get lower weight than the others.

Case Weights

In such situations, each case (x_i, y_i) is assigned a **case weight** $w_i \geq 0$:

- the higher the weight, the more important the case.
- cases with weight 0 should be treated as if they have been discarded from the data set.

Case weights can be managed as an additional pseudo-variable w in applications.

Weighted Least Squares Estimates

Formally, one tries to minimize the **weighted residual sum of squares**

$$\sum_{i=1}^n w_i (y_i - \hat{y}_i)^2 = \|\mathbf{W}^{\frac{1}{2}}(\mathbf{y} - \hat{\mathbf{y}})\|^2$$

with

$$\mathbf{W} := \begin{pmatrix} w_1 & & & 0 \\ & w_2 & & \\ & & \dots & \\ 0 & & & w_n \end{pmatrix}$$

The same argument as for the unweighted case results in the **weighted least squares estimates**

$$\mathbf{X}^T \mathbf{W} \mathbf{X} \hat{\beta} = \mathbf{X}^T \mathbf{W} \mathbf{y}$$

Weighted Least Squares Estimates / Example

To downweight the left most point, we assign case weights as follows:

w	x	y
1	5.65	3.54
1	3.37	1.75
1	1.97	0.04
1	3.70	4.42
0.1	0.15	3.85
1	8.14	8.75
1	7.42	8.11
1	6.59	5.64
1	1.77	0.18
1	7.74	8.30

Summary

- For regression, **linear models** of type $Y = \langle X, \beta \rangle + \epsilon$ can be used to predict a quantitative Y based on several (quantitative) X .
- The **ordinary least squares estimates (OLS)** are the parameters with minimal residual sum of squares (RSS). They coincide with the **maximum likelihood estimates (MLE)**.
- OLS estimates can be computed by solving the **system of linear equations** $\mathbf{X}^T \mathbf{X} \hat{\beta} = \mathbf{X}^T \mathbf{Y}$.
- The **variance of the OLS estimates** can be computed likewise $((\mathbf{X}^T \mathbf{X})^{-1} \hat{\sigma}^2)$.
- For deciding about inclusion of predictors as well as of powers and interactions of predictors in a model, **model selection measures** (AIC, BIC) and different search strategies such as forward and backward search are available.
