## Syllabus

Fri. 27.10. (1) 0. Introduction
A. Supervised Learning: Linear Models \& Fundamentals

Fri. 3.11. (2) A. 1 Linear Regression
Fri. 10.11. (3) A. 2 Linear Classification
Fri. 17.11. (4) A. 3 Regularization
Fri. 24.11. (5) A.4 High-dimensional Data

## B. Supervised Learning: Nonlinear Models

Fri. 1.12.
(6) B. 1 Nearest-Neighbor Models

Fri. 8.12.
(7) B. 2 Neural Networks

Fri. 15.12.
(8) B. 3 Decision Trees

Fri. 12.1.
(9) B. 4 Support Vector Machines

Fri. 19.1. (10) B. 5 A First Look at Bayesian and Markov Networks

## C. Unsupervised Learning

Fri. 26.1. (11) C. 1 Clustering
Fri. 2.2. (12) C. 2 Dimensionality Reduction
Fri. 9.2. (13) C. 3 Frequent Pattern Mining

## Outline

## 1. The Problem of Overfitting

2. Model Selection

## 3. Regularization

## 4. Hyperparameter Optimization

## Outline

1. The Problem of Overfitting
2. Model Selection
3. Regularization

## 4. Hyperparameter Optimization

## Fitting of models

Linear model (RSS= 11353.52)

Quadratic model (RSS= 10824.72)

Polynomial model (RSS= 7029.37 )

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

## Underfitting/Overfitting

## Underfitting:

- the model is not complex enough to explain the data well.
- results in poor predictive performance.

## Overfitting:

- the model is too complex, it describes the
- noise instead of the
- underlying relationship between target and predictors.
- results in poor predictive performance as well.

Remark: Given $N$ points $\left(x_{n}, y_{n}\right)$ without repeated measurements (i.e. $\left.x_{n} \neq x_{m}, \quad n \neq m\right)$, there exists a polynomial of degree $N-1$ with RSS equal to 0 .

## Outline

## 1. The Problem of Overfitting

## 2. Model Selection

## 3. Regularization

## 4. Hyperparameter Optimization

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

## Losses and Fit Measures

| semantics <br> goal | loss the smaller, the better minimize | fit/quality measure the larger, the better maximize |
| :---: | :---: | :---: |
| regression | $\begin{aligned} & \operatorname{RSS}(y, \hat{y}) \\ & :=\sum_{n=1}^{N}\left(y_{n}-\hat{y}_{n}\right)^{2} \\ & \operatorname{RMSE}(y, \hat{y}) \\ & :=\left(\frac{1}{N} \sum_{n=1}^{N}\left(y_{n}-\hat{y}_{n}\right)^{2}\right)^{\frac{1}{2}} \\ & \operatorname{MAE}(y, \hat{y}) \\ & :=\frac{1}{N} \sum_{n=1}^{N}\left\|y_{n}-\hat{y}_{n}\right\| \end{aligned}$ | $\begin{aligned} & \log L_{\mathcal{N}}(y, \hat{y}) \\ & :=\sum_{n=1}^{N}-\frac{1}{2 \sigma_{y}^{2}}\left(y_{n}-\hat{y}_{n}\right)^{2} \end{aligned}$ |
| classification | $\begin{aligned} & \operatorname{MR}(y, \hat{y}) \\ & :=\sum_{n=1}^{N} \mathbb{I}\left(y_{n} \neq \hat{y}_{n}\right) \end{aligned}$ | $\begin{aligned} & \mathrm{ACC}(y, \hat{y}) \\ & :=\sum_{n=1}^{N} \mathbb{I}\left(y_{n}=\hat{y}_{n}\right) \\ & \log L_{\text {binomial }}(y, \hat{y}) \\ & :=\sum_{n=1}^{N} \pi \mathbb{I}\left(y_{n}=\hat{y}_{n}\right) \\ & \quad+(1-\pi) \mathbb{I}\left(y_{n} \neq \hat{y}_{n}\right) \end{aligned}$ |

## Model Selection Measures

Model selection: given a set of models, e.g.,

$$
Y=\sum_{m=0}^{p-1} \beta_{m} X_{m}
$$

indexed by $p$ (i.e., one model for each value of $p$ ), make a choice which model describes the data best.
If we just look at losses / fit measures such as RSS, then the larger $p$, the better the fit
or equivalently

$$
\text { the larger } p \text {, the lower the loss }
$$

as the model with $p$ parameters can be reparametrized in a model with $p^{\prime}>p$ parameters by setting

$$
\beta_{m}^{\prime}=\left\{\begin{array}{cc}
\beta_{m}, & \text { for } m \leq p \\
0, & \text { for } m>p
\end{array}\right.
$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

Machine Learning

## Model Selection Measures

One uses model selection measures of type

$$
\text { model selection measure }=\text { fit }- \text { complexity } \quad(\max !)
$$

or equivalently
model selection measure $=$ loss + complexity $\quad(\min !)$

The smaller the loss ( $=$ lack of fit), the better the model.

The smaller the complexity, the simpler and thus better the model.

The model selection measure tries to find a trade-off between fit/loss and complexity.

## Model Selection Measures

Akaike Information Criterion (AIC):
(maximize)

$$
\operatorname{AIC}:=\log L-p
$$

or (minimize)

$$
\text { AIC }:=-2 \log L+2 p
$$

## Bayes Information Criterion (BIC) /

Bayes-Schwarz Information Criterion: (maximize)

$$
\mathrm{BIC}:=\log L-\frac{p}{2} \log N
$$

where $L$ denotes the likelihood, $N$ the number of samples.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

## Variable Backward Selection

\{ A, F, H, I, J, L, P \}<br>AIC $=63.01$

## Variable Backward Selection

## Variable Backward Selection

```
    {A,F,H,I, J,L, P }
    AIC = 63.01
{X,F,H,I,J,L,P} ... {A,F,H,X,J,L,P } ... {A,F,H,I,J,L, X}
    AIC=63.87 AIC=61.11
    {X,F,H,X,J,L,P} ... {A,F,M,X,J,L,P } ... {A,F,H,X,J,L, 仅}
        AIC=61.88
                        AIC=59.40
        AIC=68.70
```

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

Machine Learning

## Outline

## 1. The Problem of Overfitting

## 2. Model Selection

## 3. Regularization

## 4. Hyperparameter Optimization

## Shrinkage

Model selection operates by

1. fitting model instances for a set of models with varying complexity
2. picking the "best one" ex post,

## Variable Selection

- = model selection applied to models with different predictor subsets
- for models $\hat{y}$ that factor through a linear combination of the predictors,

$$
\hat{y}(x ; \hat{\beta})=f\left(\sum_{m=1}^{M} \hat{\beta}_{m} x_{m}\right) \quad \text { for a suitable } f
$$

- dropping a variable $x_{m}$ from the model is equivalent to
- forcing its model parameter $\hat{\beta}_{m}$ to be 0 .

Note: "Fitting a model instance" = "Learning model parameters", for models having parameters such as linear regression, logistic regression etc.
Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

Machine Learning

## Shrinkage

## Variable Selection

- . .
- forcing its model parameter $\hat{\beta}_{m}$ to be 0 .

Shrinkage follows a similar idea:

- smaller parameters mean a simpler hypothesis/less complex model.
- hence, small parameters should be prefered in general.
- a term is added to the objective function to
- favor small parameters or equivalently
- penalize large parameters or
- shrink them towards 0
instead of forcing them to be 0 .

## Shrinkage

There are various types of shrinkage techniques for different application domains.

L1/Lasso Regularization: $\lambda \sum_{m=1}^{M}\left|\hat{\beta}_{m}\right|=\lambda\|\hat{\beta}\|_{1}$
L2/Tikhonov Regularization: $\lambda \sum_{m=1}^{M} \hat{\beta}_{m}^{2}=\lambda\|\hat{\beta}\|_{2}^{2}$
Elastic Net: $\lambda_{1}\|\hat{\beta}\|_{1}+\lambda_{2}\|\hat{\beta}\|_{2}^{2}$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

## Ridge Regression

Ridge regression is a combination of

$$
\begin{aligned}
& \underbrace{\sum_{n=1}^{N}\left(y_{n}-\hat{y}_{n}\right)^{2}}+\lambda \underbrace{\sum_{m=1}^{M} \beta_{m}^{2}} \\
& =\mathrm{L} 2 \text { loss } \quad+\lambda \mathrm{L} 2 \text { regularization }
\end{aligned}
$$

## Ridge Regression (Closed Form)

Ridge regression: minimize

$$
\begin{aligned}
& \operatorname{RSS}_{\lambda}(\hat{\beta})=\operatorname{RSS}(\hat{\beta})+\lambda \sum_{j=1}^{p} \hat{\beta}_{j}^{2}=\langle\mathbf{y}-\mathbf{X} \hat{\beta}, \mathbf{y}-\mathbf{X} \hat{\beta}\rangle+\lambda \sum_{j=1}^{p} \hat{\beta}_{j}^{2} \\
& \Rightarrow \hat{\beta}=\left(\mathbf{X}^{T} \mathbf{X}+2 \lambda I\right)^{-1} \mathbf{X}^{T} \mathbf{y}, \quad I:=\left(\begin{array}{cccc}
1 & 0 & \cdots & 0 \\
0 & 1 & \ddots & \vdots \\
\vdots & \ddots & \ddots & 0 \\
0 & \cdots & 0 & 1
\end{array}\right)
\end{aligned}
$$

with $\lambda \geq 0$ a complexity parameter / regularization parameter.
Beware: ridge regression parameter estimates are not equivariant under scaling of the predictors
$\rightsquigarrow$ data should be normalized before parameter estimation:

$$
x_{n, m}^{\prime}:=\frac{x_{n, m}-\bar{x}_{,, m}}{\hat{\sigma}\left(x_{., m}\right)}
$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

Machine Learning

## Ridge Regression (Gradient Descent)

learn-ridgereg-GD( $\left.\mathcal{D}^{\text {train }}:=\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{N}, y_{N}\right)\right\}, \alpha, t_{\text {max }} \in \mathbb{N}, \epsilon \in \mathbb{R}^{+}\right)$:
$X:=\left(x_{1}, x_{2}, \ldots, x_{N}\right)^{T}$
$y:=\left(y_{1}, y_{2}, \ldots, y_{N}\right)^{T}$
$\hat{\beta}:=0_{M}$
$\ell:=\|y-X \hat{\beta}\|^{2}$
for $t=1, \ldots, t_{\text {max }}$ :
$\hat{\beta}:=\hat{\beta}-\alpha\left(-2 \cdot X^{\top}(y-X \hat{\beta})+2 \lambda \hat{\beta}\right)$
$\ell^{\text {old }}:=\ell$
$\ell:=\|y-X \hat{\beta}\|^{2}$
if $\ell-\ell^{\text {old }}<\epsilon$ :
return $\hat{\beta}$
raise exception "not converged in $t_{\text {max }}$ iterations"

## L2-Regularized Update Rule

$$
\hat{\beta}^{(t)}:=\underbrace{(1-2 \alpha \lambda)}_{\text {shrinkage }} \hat{\beta}^{(t-1)}-\alpha\left(-2 X^{\top}\left(y-X \hat{\beta}^{(t-1)}\right)\right)
$$

## Tikhonov Regularization Derivation (1/2)

Treat the true parameters $\theta_{j}$ as random variables $\Theta_{j}$ with the following distribution (prior):

$$
\Theta_{j} \sim \mathcal{N}\left(0, \sigma_{\Theta}\right), \quad j=1, \ldots, p
$$

Then the joint likelihood of the data and the parameters is

$$
L_{\mathcal{D}, \Theta}(\theta):=\left(\prod_{n=1}^{N} p\left(x_{n}, y_{n} \mid \theta\right)\right) \prod_{j=1}^{p} p\left(\Theta_{j}=\theta_{j}\right)
$$

and the conditional joint log likelihood of the data and the parameters

$$
\log L_{\mathcal{D}, \Theta}^{\text {cond }}(\theta):=\left(\sum_{n=1}^{N} \log p\left(y_{n} \mid x_{n}, \theta\right)\right)+\sum_{j=1}^{p} \log p\left(\Theta_{j}=\theta_{j}\right)
$$

and

$$
\log p\left(\Theta_{j}=\theta_{j}\right)=\log \frac{1}{\sqrt{2 \pi} \sigma_{\Theta}} e^{-\frac{\theta_{j}^{2}}{2 \sigma_{\Theta}^{2}}}=-\log \left(\sqrt{2 \pi} \sigma_{\Theta}\right)-\frac{\theta_{j}^{2}}{2 \sigma_{\Theta}^{2}}
$$

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

Machine Learning

## Tikhonov Regularization Derivation (2/2)

Dropping the terms that do not depend on $\theta_{j}$ yields:

$$
\begin{aligned}
\log L_{\mathcal{D}, \Theta}^{\text {cond }}(\theta) & :=\left(\sum_{n=1}^{N} \log p\left(y_{n} \mid x_{n}, \theta\right)\right)+\sum_{j=1}^{p} \log p\left(\Theta_{j}=\theta_{j}\right) \\
& \propto\left(\sum_{n=1}^{N} \log p\left(y_{n} \mid x_{n}, \theta\right)\right)-\frac{1}{2 \sigma_{\Theta}^{2}} \sum_{j=1}^{p} \theta_{j}^{2}
\end{aligned}
$$

This also gives a semantics to the complexity / regularization parameter $\lambda$ :

$$
\lambda=\frac{1}{2 \sigma_{\Theta}^{2}}
$$

but $\sigma_{\Theta}^{2}$ is unknown. (We will see methods to estimate $\lambda$ soon.)
The parameters $\theta$ that maximize the joint likelihood of the data and the parameters are called Maximum Aposteriori Estimators (MAP estimators).

## L2-Regularized Logistic Regression (Gradient Descent)

$$
\log L_{\mathcal{D}}^{\text {cond }}(\hat{\beta})=\sum_{n=1}^{N} y_{n}\left\langle X_{n}, \hat{\beta}\right\rangle-\log \left(1+e^{\left\langle X_{n}, \hat{\beta}\right.}\right)-2 \lambda \sum_{j=1}^{P} \hat{\beta}_{j}^{2}
$$

1: procedure Log-REGR-

$$
\begin{array}{ll} 
& \mathrm{GA}\left(L_{\mathcal{D}}^{\text {cond }}: \mathbb{R}^{P+1} \rightarrow \mathbb{R}, \hat{\beta}^{(0)} \in \mathbb{R}^{P+1}, \alpha, t_{\max } \in \mathbb{N}, \epsilon \in \mathbb{R}^{+}\right) \\
2: & \text { for } t=1, \ldots, t_{\max } \text { do } \\
3: & \hat{\beta}_{0}^{(t)}:=\hat{\beta}_{0}^{(t-1)}+\alpha \sum_{n=1}^{N}\left(y_{n}-p\left(Y=1 \mid X=x_{n} ; \hat{\beta}^{(t-1)}\right)\right) \\
\text { 4: } & \text { for } j=1, \ldots, P \text { do } \\
\text { 5: } & \hat{\beta}_{j}^{(t)}:= \\
& \hat{\beta}_{j}^{(t-1)}+\alpha\left(\sum_{n=1}^{N} x_{n, j}\left(y_{n}-p\left(Y=1 \mid X=x_{i} ; \hat{\beta}^{(t-1)}\right)\right)-2 \lambda \hat{\beta}_{j}^{(t-1)}\right)
\end{array}
$$

$$
3:
$$

4:

6 :
7: $\quad$ return $\hat{\beta}^{(t)}$
8: error " not converged in $t_{\text {max }}$ iterations"

## L2-Regularized Logistic Regression (Newton)

Newton update rule:

$$
\begin{gathered}
\hat{\beta}^{(t)}:=\hat{\beta}^{(t-1)}+\alpha H^{-1} \nabla_{\hat{\beta}} p\left(Y=1 \mid X=x_{i} ; \hat{\beta}^{(t-1)}\right) \\
p_{i}=p\left(Y=1 \mid X=x_{i} ; \hat{\beta}^{(t-1)}\right) \\
\nabla_{\hat{\beta}} L_{\mathcal{D}}^{\text {cond }}=\left(\begin{array}{c}
\sum_{n=1}^{N}-\left(y_{n}-p_{n}\right) \\
\sum_{n=1}^{N}-x_{n, 1}\left(y_{n}-p_{n}\right)-2 \lambda \hat{\beta}_{1} \\
\vdots \\
\sum_{n=1}^{N}-x_{n, P}\left(y_{n}-p_{n}\right)-2 \lambda \hat{\beta}_{P}
\end{array}\right) \\
H=\sum_{n=1}^{N}-p_{n}\left(1-p_{n}\right) x_{n} x_{n}^{T}-2 \lambda I
\end{gathered}
$$

## Outline

## 1. The Problem of Overfitting

2. Model Selection
3. Regularization
4. Hyperparameter Optimization

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

## What is Hyperparameter Optimization?

- Most models and learning algorithms have parameters that cannot be learned by minimizing the objective function, because either
- the objective function would be minimized for a trivial value, e.g., $\lambda=0$, or
- the parameters affect the learning algorithm, e.g., learning rate.
- These parameters are called hyperparameters $\lambda$ and they parametrize a learning algorithm $\mathcal{A}_{\lambda}$.
- choose suitable hyperparameters $\lambda$
- use $\mathcal{A}_{\lambda}$ to map the training data $\mathcal{D}_{\text {train }}$ to a prediction function $\hat{y}$ by minimizing some loss $\mathcal{L}(\mathcal{D}, \hat{y})$ over the training data.

## What is Hyperparameter Optimization?

- Identifying good values for the hyperparameters $\lambda$ is called hyperparameter optimization.
- hyperparameter optimization is a second level optimization

$$
\underset{\lambda \in \Lambda}{\arg \min } \mathcal{L}\left(\mathcal{D}_{\text {valid }}, \mathcal{A}_{\lambda}\left(\mathcal{D}_{\text {train }}\right)\right)=\underset{\lambda \in \Lambda}{\arg \min } \Psi(\lambda)
$$

where

- $\Psi$ is the hyperparameter response function and
- $\mathcal{D}_{\text {valid }}$ a validation data (aka calibration data and holdout data).

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

## Why Hyperparameter Optimization

- So far only model parameters were optimized.
- Values for hyperparameters (such as regularization $\lambda$ and learning rate $\alpha$ ) came "out of the blue".
- Hyperparameters can have a big impact on the prediction quality.

## Grid Search

- Assume we have $Q$ hyperparameters $\lambda_{1}, \ldots, \lambda_{Q}$
- Choose for each hyperparameter $\lambda_{q}$ a set of values $\Lambda_{q}$.
- $\Lambda:=\prod_{q=1}^{Q} \Lambda_{q}$ is then a grid of hyperparameters.
- Choose the hyperparameter combination $\lambda \in \Lambda$ with best performance on $\mathcal{D}_{\text {valid }}$.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

## Random Search

- Instead of trying hyperparameter combinations on a grid, try random hyperparameter combinations $\lambda$ for $\Lambda$ (within a reasonable range).
- Usually slightly better results than grid search.

## What is the Validation Data?

- Whenever a learning process depends on a hyperparameter, the hyperparameter can be estimated by picking the value with the lowest error.
- If this is done on test data, one actually uses test data in the training process ("train on test"), thereby lessen its usefulness for estimating the test error.
- Therefore, one splits the training data again in
- (proper) training data and
- validation data.
- The validation data figures as test data during the training process.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany
Machine Learning

## Cross Validation

Instead of a single split into
training data, (validation data,) and test data
K-fold cross validation splits the data in $K$ parts (of roughly equal size)

$$
\mathcal{D}=\mathcal{D}_{1} \cup \mathcal{D}_{2} \cup \cdots \cup \mathcal{D}_{K}, \quad \mathcal{D}_{k} \text { pairwise disjoint }
$$

and averages performance over $K$ learning problems

$$
\mathcal{D}_{\text {train }}^{(k)}:=\mathcal{D} \backslash \mathcal{D}_{k}, \quad \mathcal{D}_{\text {test }}^{(k)}:=\mathcal{D}_{k} \quad k=1, \ldots, K
$$

Common is 5 - and 10 -fold cross validation.
$N$-fold cross validation is also known as leave one out.

## Cross Validation

How many folds to use in $K$-fold cross validation? $K=N /$ leave one out:

- approximately unbiased for the true prediction error.
- high variance as the $N$ training sets are very similar.
- in general computationally costly as $N$ different models have to be learnt.
$K=5:$
- lower variance.
- bias could be a problem, due to smaller training set size the prediction error could be overestimated.

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany

## Summary

- The problem of underfitting can be overcome by using more complex models, e.g., having
- variable interactions as in polynomial models.
- The problem of overfitting can be overcome by
- model selection / variable selection as well as by
- (parameter) shrinkage.
- Applying L2-regularization to Linear and Logistic Regression requires only few changes in the learning algorithm
- Shrinkage introduces a hyperparameter $\lambda$ that cannot be learned by direct loss minimization.
- Estimating the best hyperparameters can be considered as a meta-learning problem. They can be estimated e.g. by
- Grid Search or
- Random Search.
