& Institute of Computer Science  
University of Hildesheim  
<http://www.ismll.uni-hildesheim.de>

## II. XML / 6. XML Query Language (XQuery)

### 1. Creating Nodes of the Result Tree

### 2. FLWOR expressions

### 3. Variables and Functions

### 4. Types and Static Type Checking

## XQuery Specification

XQuery is specified in

1. XQuery 1.0: An XML Query Language (Rec 2007/01/23) and
2. XML Syntax for XQuery 1.0 (XQueryX; (Rec 2007/01/23)

as well as documents about requirements, use cases, serialization, and formal semantics.

XQuery **extends** XPath 2.0, i.e., (most) any XPath expressions **are** XQuery "queries"

XQuery does not have an XML Syntax  
(like XPath, but contrary to XSLT).

## XQuery Modules

The XQuery processing unit is the **module**:

```
<Module> := ( xquery version <StringLiteral> ; )?
  ( <ModuleDecl> ; )?
  <Prolog>
  <Expr>
```

Usually one module is stored in one file.

**Library modules** have a module declaration, but no body expression;  
**main modules** have a body expression, but no module declaration.

All XPath expressions are XQuery expressions *<Expr>*.

```
xquery version "1.0" ;
 $\text{\#}2//title[contains(string(.),"XML")]/..//author$ 
```

Figure 1: Example XQuery consisting of an XPath expression.

## Literal Result Nodes

Like in XSLT, nodes can be created in two ways:

1. literal result elements (called **direct constructors** in the XQuery spec), their attributes, namespaces and nested character data is copied literally to the result tree.

XML comments and PIs can be created in the same way (as XQuery does not have an XML syntax).

```

1 xquery version "1.0" ;
2 <article author="John Doe" version="2004/06/07">
3   <title>What <em>others</em> say</title>
4   A <em>short</em><!-- 20 pages--> overview ...
5 </article>
```

Figure 2: Example XQuery consisting of literal result items only.

## Literal Result Node Sequences

```

1 xquery version "1.0" ;
2 <!-- first ideas -->,
3 <?xmlstylesheet href='article.css' type='text/css'?>,
4 <article author="John Doe" version="2004/06/07">
5   <title>What <em>others</em> say</title>
6   A <em>short</em><!-- 20 pages--> overview ...
7 </article>
```

Figure 3: Example XQuery consisting of literal result items almost only.

## Computed Result Nodes

2. computed result nodes (called **computed constructors** in the XQuery spec):

```
<computedConstructor> := document { <Expr>? }
| element <QName> { <Expr>? }
| attribute <QName> { <Expr>? }
| text { <Expr>? }
| comment { <Expr>? }
| processing-instruction <NCName> { <Expr>? }
| namespace <NCName> { <Expr>? }
```

`<QName>` and `<NCName>` can also be replaced by `{ <Expr> }`.

## Computed Result Nodes

```
1 <?xml version="1.1"?>
2 <!-- first ideas -->
3 <?xmlstylesheet href='article.css' type='text/css'?>
4 <article author="John Doe" version="2004/06/07">
5   <title>What <em>others</em> say</title>
6   A <em>short</em><!-- 20 pages--> overview ...
7 </article>
```

Figure 4: Sample XML document.

```
1 xquery version "1.0" ;
2 for $a in //article return
3   element article {
4     for $att in $a/@* return
5       element { name($att) } { string($att) },
6       element title { string($a/title) }
7 }
```

Figure 5: XQuery `element.xq` creating elements with fixed and computed names.

```
1 <?xml version="1.0" encoding="UTF-8"?>
2 <article>
3   <author>John Doe</author>
4   <version>2004/06/07</version>
5   <title>What others say</title>
6 </article>
```

Figure 6: Result document of the query.

## Nesting Computed Result Nodes in Literal Result Nodes

In

- values of attributes and
- the contents

of literal result elements, expressions of type

{ *<Expr>* }

can be used to insert computed items (for attribute values) or nodes (for element content).

```

1xquery version "1.0" ;
2for $a in //article return
3  <article>
4    { for $att in $a/@* return
5      element { name($att) } { string($att) },
6      <title>{ string($a/title) }</title>
7    }
8  </article>
```

Figure 7: XQuery creating elements with fixed and computed names.

If in these contexts "{" or "}" should appear literally, the symbols must be escaped as "{{" and "}}".

Lars Schmidt-Thieme, Information Systems and Machine Learning Lab (ISMLL), University of Hildesheim, Germany,  
Course on XML and Semantic Web Technologies, summer term 2009

7/33

## Performing XQuery Queries by Saxon

XQuery queries can be performed, e.g., by Saxon.

call (with saxon8.jar in classpath):

```
java net.sf.saxon.Query -s anarticle.xml element.xq
```

## II. XML / 6. XML Query Language (XQuery)

### 1. Creating Nodes of the Result Tree

### 2. FLWOR expressions

### 3. Variables and Functions

### 4. Types and Static Type Checking

## XML and Semantic Web Technologies / 2. FLWOR expressions

### Clauses

```

⟨FLWORExpr⟩ := (⟨ForClause⟩ | ⟨LetClause⟩)+  

    ⟨where ⟨ExprSingle⟩)? ⟨OrderByClause⟩?  

    ⟨return ⟨Expr⟩

⟨ForClause⟩ := for  

    $ ⟨QName⟩ (as ⟨SequenceType⟩)? (at $ ⟨QName⟩)? in ⟨Expr⟩  

    (, $ ⟨QName⟩ (as ⟨SequenceType⟩)? (at $ ⟨QName⟩)? in ⟨Expr⟩)*

⟨LetClause⟩ := let $ ⟨QName⟩ (as ⟨SequenceType⟩)? := ⟨Expr⟩  

    (, $ ⟨QName⟩ (as ⟨SequenceType⟩)? := ⟨Expr⟩)*
  
```

XPath's for-expressions is a special case of an XQuery FLWOR expression.  
New is:

- `let` binds additional variables,
- `where` filters tuples,
- `order by` orders tuples,
- `at $` `⟨QName⟩` binds an additional positional variable,
- `as` `⟨SequenceType⟩` types the for-/let-variable.

```

1 xquery version "1.0" ;
2 for $s in (<one/>, <two/>, <three/>)
3   return <out>{$s}</out>

```

Figure 8: FLWOR-expression using `for`.

```

1 xquery version "1.0" ;
2 let $s := (<one/>, <two/>, <three/>)
3   return <out>{$s}</out>

```

Figure 9: FLWOR-expression using `let`.

```

1 <?xml version="1.0"?>
2 <out>
3   <one/>
4 </out>
5 <out>
6   <two/>
7 </out>
8 <out>
9   <three/>
10 </out>

```

Figure 10: Result of `for`-expression.

```

2 let $inputvalues := 1 to 1000 return
3   avg($inputvalues[position() mod 100 = 0]
4 ]

```

Figure 13: Same query using a predicate.

550

Figure 14: Result of the queries.

## order by Clause

```

⟨OrderByClause⟩ := (order by | stable order by) ⟨OrderSpecList⟩
⟨OrderSpecList⟩ := ⟨OrderSpec⟩ (, ⟨OrderSpec⟩)*
⟨OrderSpec⟩ := ⟨Expr⟩ ⟨OrderModifier⟩
⟨OrderModifier⟩ := ( ascending | descending )?
( empty greatest | empty least )?
  
```

```

1 xquery version "1.0" ;
2 <html><body>
3 Authors: <ol>
4 { for $a in distinct-values{//author)
5   let $sn := substring-after($a, ' '),
6     $fn := substring-before($a, ' ')
7   order by $sn, $fn
8   return <li>{ concat($sn, ", ", $fn) }</li>
9 }
10 </ol></body></html>
11
  
```

```

1 <html>
2   <body>
3     Authors:
4     <ol>
5       <li>Eckstein, Rainer</li>
6       <li>Eckstein, Silke</li>
7       <li>Muellner, Leonard</li>
8       <li>T. Ray, Erik</li>
9       <li>Walsh, Norman</li>
10      </ol>
11    </body>
  
```

Course on XML and Semantic Web Technologies, summer term 2009

Figure 16: Result of the query on the books.xml document.

12/33

## Positional Variable with at

at allows to bind the position of the actual item to a variable.

This is the only possibility to access the position  
(as the XPath function `position()` retrieves the position of the context item only).

```

1 xquery version "1.0" ;
2 <books>{
3   for $b at $no in //book return
4     <book no="{$no}">{ string($b/title) }</book>
5 }</books>
  
```

## II. XML / 6. XML Query Language (XQuery)

### 1. Creating Nodes of the Result Tree

### 2. FLWOR expressions

### 3. Variables and Functions

### 4. Types and Static Type Checking

$$\langle \text{Prolog} \rangle := ((\langle \text{Setter} \rangle \mid \langle \text{ImportDecl} \rangle \mid \langle \text{ImportSchemaDecl} \rangle \mid \langle \text{NamespaceDecl} \rangle ; )^* ((\langle \text{VarDecl} \rangle \mid \langle \text{FunctionDecl} \rangle \mid \langle \text{OptionDecl} \rangle ) ; )^*$$

$$\langle \text{NamespaceDecl} \rangle := \text{declare namespace } \langle \text{NCName} \rangle = \langle \text{StringLiteral} \rangle \mid \text{declare default element namespace } \langle \text{StringLiteral} \rangle \mid \text{declare default function namespace } \langle \text{StringLiteral} \rangle$$

$$\langle \text{VarDecl} \rangle := \text{declare variable } \$ \langle \text{QName} \rangle (\text{as } \langle \text{SequenceType} \rangle)? ((:= \langle \text{Expr} \rangle) \mid \text{external})$$

XQuery variables are read-only.

Alternatively, variables can be bound with a let-clause of a FLWOR-expression.

```

1 xquery version "1.0" ;
2 declare variable $no := 0 ;
3 <books>{
4   for $b in //book
5   let $no := $no + 1 return
6     <book no="{$no}">{ string($b/title) }</book>
7 }</books>
```

Figure 19: What might happen here?

```

1 <?xml version="1.0" encoding="UTF-8"?>
2 <books>
3   <book no="1">XML und Datenmodellierung</book>
4   <book no="1">Learning XML</book>
5   <book no="1">DocBook: The Definitive Guide</book>
6 </books>

```

Figure 20: Result of broken query on last slide.

## Defining Functions

$$\begin{aligned} \langle FunctionDecl \rangle &:= \text{declare function } \langle QName \rangle \ ( \langle ParamList \rangle ? ) \\ &\quad ( \text{as } \langle SequenceType \rangle )? (\{ \langle Expr \rangle \} | \text{external}) \\ \langle ParamList \rangle &:= \langle Param \rangle ( , \langle Param \rangle )^* \\ \langle Param \rangle &:= \$ \langle QName \rangle ( \text{as } \langle SequenceType \rangle )? \end{aligned}$$

```

1 xquery version "1.0";
2 declare namespace f = "http://www.cgnm.de/xml/xquery/functions";
3 declare function f:shortauthor($author as node()) {
4   let $numAuthors := count($author) return
5     concat($author[1], if ($numAuthors=2) then concat(' and ', $author[2])
6           else if ($numAuthors>=3) then ' et al.' else '')
7 };
8 <html><body><ol>
9   { for $b in //book return
10     <li>{ concat(f:shortauthor($b/author), ": ", string($b/title), ", ", $b/year) }</li>
11   }</ol></body></html>

```

Figure 21: Function declaration.

For Saxon, names of user-defined functions must have a namespace.

## Defining Functions

```

1 <html>
2   <body>
3     <ol>
4       <li>Rainer Eckstein and Silke Eckstein: XML und Datenmodellierung, 2004</li>
5       <li>Erik T. Ray: Learning XML, 2003</li>
6       <li>Norman Walsh and Leonard Muellner: DocBook: The Definitive Guide, 1999</li>
7     </ol>
8   </body>
9 </html>

```

Figure 22: Result of query on last slide.

## Library Modules

```

<ModuleDecl> := module namespace <NCName> = <StringLiteral>
<ImportDecl> := import module (namespace <NCName> =)? <StringLiteral>
  (at <StringLiteral>)?

```

```

1 xquery version "1.0" ;
2 module namespace f = "http://www.cgnm.de/xml/xquery/functions";
3 declare function f:shortauthor($author as node()) {
4   let $numAuthors := count($author) return
5     concat($author[1], if ($numAuthors=2) then concat(' and ', $author[2])
6           else if ($numAuthors>=3) then ' et al.' else "")
7 };

```

Figure 23: Library module `biblib.xq`.

```

1 xquery version "1.0" ;
2 import module namespace f = "http://www.cgnm.de/xml/xquery/functions" at "biblib.xq";
3 <html><body><ol>
4   { for $b in //book return
5     <li>{ concat(f:shortauthor($b/author), ": ", string($b/title), ", ", $b/year) }</li>
6   }</ol></body></html>

```

Figure 24: Query importing a library module.

## II. XML / 6. XML Query Language (XQuery)

### 1. Creating Nodes of the Result Tree

### 2. FLWOR expressions

### 3. Variables and Functions

### 4. Types and Static Type Checking

## XML and Semantic Web Technologies / 4. Types and Static Type Checking

### Working with Types

To use types defined in a schema, e.g., as

- types of variables,
- as types of function parameters or return types,
- in cast expressions, etc.

the namespace of the schema defining the types has to be declared.

```

1 xquery version "1.0" ;
2 declare namespace f = "http://www.cgnm.de/xml/xquery/functions";
3 declare namespace xs="http://www.w3.org/2001/XMLSchema";
4
5 declare function f:shortauthor($author as node()) as xs:string {
6   let $numAuthors := count($author) return
7     concat($author[1], if ($numAuthors=2) then concat(' and ', $author[2])
8           else if ($numAuthors>=3) then ' et al.' else '')
9   };
10 <html><body><ol>
11 { for $b in //book return
12   <li>{ concat(f:shortauthor($b/author), ": ", string($b/title), ", ", $b/year) }</li>
13 }</ol></body></html>
```

Figure 25: Working with XML Schema types.

## Validating and Static Type Checking (1/5)

```

1  <?xml version="1.0"?>
2  <xss: schema version="1.0" xmlns:xs="http://www.w3.org/2001/XMLSchema"
3      targetNamespace="http://www.cgnm.de/xml/books.xsd"
4      xmlns="http://www.cgnm.de/xml/books.xsd"
5      elementFormDefault="qualified">
6  <xss:element name="books">
7      <xss:complexType>
8          <xss:sequence maxOccurs="unbounded">
9              <xss:element ref="book"/>
10             </xss:sequence>
11         </xss:complexType>
12     </xss:element>
13     <xss:element name="book">
14         <xss:complexType>
15             <xss:sequence>
16                 <xss:element name="author" minOccurs="1" maxOccurs="unbounded"
17                     type="xs:string"/>
18                 <xss:element name="title" type="xs:string"/>
19                 <xss:element name="year" type="xs:string"/>

23 </xsesequence>
24 </xsccomplexType>
25 </xselement>
26 </xsschema>

```

Figure 28: XML Schema of the target document.

## Validating and Static Type Checking (3/5)

```

1 xquery version "1.0" ;
2 declare namespace f = "http://www.cgnm.de/xml/xquery/functions";
3 declare function f:shortauthor($author as node()) {
4   let $numAuthors := count($author) return
5     concat($author[1], if ($numAuthors=2) then concat(' and ', $author[2])
6           else if ($numAuthors>=3) then ' et al.' else "")
7 };
8 <html><body><ol>
9   { for $b in //book return
10     <item>{ concat(f:shortauthor($b/auhtor), ": ", string($b/title), ", ", $b/year) }</item>
11   }</ol></body></html>

```

Figure 29: Query containing errors w.r.t. schemata.

## Validating and Static Type Checking (3.5/5)

```

<html>
  <body>
    <ol>
      <item>: XML und Datenmodellierung, 2004</item>
      <item>: Learning XML, 2003</item>
      <item>: DocBook: The Definitive Guide, 1999</item>
    </ol>
  </body>
</html>

```

Figure 30: Result of broken query on last slide.

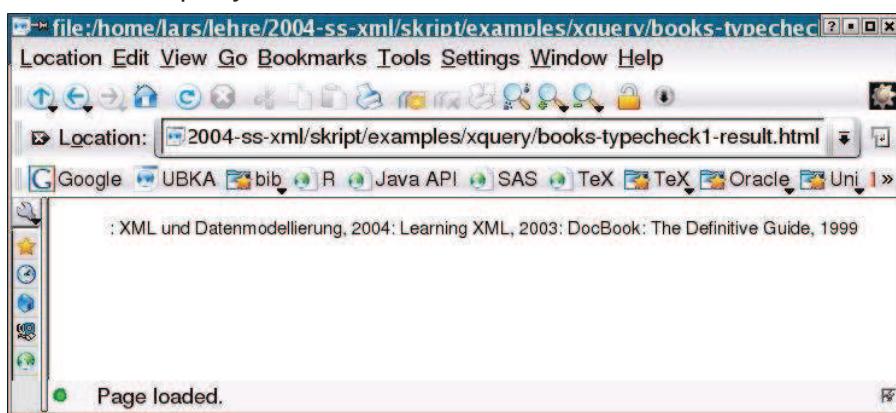

Figure 31: Result viewed in HTML browser.

## Kinds of Validation

Validity of specific input documents can be checked by the parser.

Validity of specific output documents can be checked by:

1. validating output as a post-process or by,
2. validating output while it is generated.

This is called **dynamic type checking** (depends on data, done at runtime) as opposed to **static type checking** (does not depend on data, done at query compile time).

## Validate Expressions

```

<ImportSchemaDecl> := import schema <SchemaPrefix>? <StringLiteral>
  (at <StringLiteral>)?

<SchemaPrefix> := ( namespace <NCName> = ) | default element namespace

<ValidateExpr> := validate (lax | strict)? { <Expr> }
  
```

validate returns its argument node with type annotation  
(and raises an error, if it is not valid w.r.t. its associated schema).

## Validating and Static Type Checking (4/5)

```

1 xquery version "1.0" ;
2 declare namespace f = "http://www.cgnm.de/xml/xquery/functions";
3 declare function f:shortauthor($author as node()) {
4   let $numAuthors := count($author) return
5     concat($author[1], if ($numAuthors=2) then concat(' and ', $author[2])
6           else if ($numAuthors>=3) then ' et al.' else "")
7 };
8 import schema namespace bk="http://www.cgnm.de/xml/books.xsd" at "books.xsd";
9 import schema default element namespace "http://www.cgnm.de/xml/html-toy.xsd" a
10 validate strict {
11   <html><body><ol>
12   { for $b in //bk:book return
13     <item>{ concat(f:shortauthor($b/bk:auhtor), ": ", string($b/bk:title), ", ", $b/bk:yea
14   }</ol></body></html>
15 }

```

Figure 32: Query containing errors w.r.t. schemata, with schema import.

## Validating and Static Type Checking (5/5)

```

1 xquery version "1.0" ;
2 declare namespace f = "http://www.cgnm.de/xml/xquery/functions";
3 declare function f:shortauthor($author as node()) {
4   let $numAuthors := count($author) return
5     concat($author[1], if ($numAuthors=2) then concat(' and ', $author[2])
6           else if ($numAuthors>=3) then ' et al.' else "")
7 };
8 import schema namespace bk="http://www.cgnm.de/xml/books.xsd" at "books.xsd";
9 import schema default element namespace "http://www.cgnm.de/xml/html-toy.xsd" a
10 validate strict {
11   <html><body><ol>
12   { for $b in //bk:book return
13     <li>{ concat(f:shortauthor($b/bk:author), ": ", string($b/bk:title), ", ", $b/bk:year) }
14   }</ol></body></html>
15 }

```

Figure 33: Query with errors fixed.

## Comparison XSLT–XQuery

a. commonalities:

| topic                        | details                                                                                                                                            |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0. basic expressions         | both languages extend XPath.                                                                                                                       |
| 1. variables                 | read-only                                                                                                                                          |
| 2. definition of functions   | callable in XPath expressions                                                                                                                      |
| 3. nested iterations / joins | FLWOR-expressions and for-each,<br>for-each-group                                                                                                  |
| 4. creating nodes            | both languages provide two mechanisms: <ul style="list-style-type: none"> <li>• literal result nodes,</li> <li>• computed result nodes.</li> </ul> |
| 5. type strictness           | both languages build on XML Schema and allow static type checking                                                                                  |

## Comparison XSLT–XQuery

b. differences:

| topic                     | XSLT                                                | XQuery                          |
|---------------------------|-----------------------------------------------------|---------------------------------|
| 1. syntax                 | XML                                                 | non-XML                         |
| 2. user-defined functions | can be used in expressions and in value-of          | can be used everywhere          |
| 3. FLWOR expressions      | can be replaced by combined statements (procedural) | declarative                     |
| 4. template rules         | template and apply-templates                        | —                               |
| 5. type strictness        | maybe not encouraged by templates                   | encouraged by FLWOR expressions |
